Abstract. *Experimental validations of modeling predictions are usually very expensive and time-consuming efforts even for relatively simple deterministic statements of analysis. In case of probabilistic analysis, this problem becomes even more difficult, since it may require numerous tests to generate large enough statistical populations. A solution to mitigate this challenge is developed in this study by considering large volume of measurements for each performed test. The developed approach is based on implementation of digital image correlation (DIC) technique and its integration with independent FEA modeling. According to DIC, the entire field of displacements is captured and quantified in contrast with more traditional test methods showing deformation of a few selected points only. These measured fields are considered as random functions and are compared with corresponding modeling predictions. The predictions are generated by FEA using either deterministic or probabilistic statements of modeling. A corresponding computational implementation is developed for efficient test/model integration and statistical assessment of conclusions including their confidence. Methodological challenges of the developed approach are summarized and discussed in detail. Demonstration of the developed capabilities is shown on example of composite sub-components under static load conditions. The robust nature of computational implementation is validated. It is also shown that generated statistical results provide additional advanced opportunities for a) interpretation of test results; b) critical evaluation of modeling assumptions; and c) generation of statistical data to quantify inevitable scatter of material/structural response. Although the demonstration of the approach is considered on example of composite structures, it can be equally recommended for other materials such as metals, polymers, elastomers, etc.*

1. INTRODUCTION

Experimental characterization of complex aerospace structures is usually a very expensive and time-consuming process. Particular challenges are often associated with composite structures due to their heterogeneous design, anisotropy of material properties, complex network of damage patterns, etc. Thus, all efforts should be applied to maximize output of such testing with potential applicability of generated results to other similar systems or load scenarios. Digital image correlation (DIC) technique is among the most promising ways in this direction since DIC can generate another level of information unavailable in more traditional mechanical testing. Major advantage here is generation of high fidelity *functions* of displacements or strains rather than their *limited finite measurements* in conventional characterization. Opportunities of DIC-based experimental characterization are illustrated, for example, in recent works (Gurvich et al. (2013b); Gurvich and Clavette, 2013a) for composite structures and materials, respectively. Additional key advantage of DIC is associated with large statistical population of measurements providing invaluable opportunity to perform systematic probabilistic assessment and apply generated results to uncertainty quantification. This study describes and illustrates this advantage in detail for problems of test/model validation requiring probabilistic assessment.

2. APPROACH

Developed approach is schematically illustrated at Fig.1 and consists of three major inter-connected efforts. The first effort is focused on development and implementation of finite-element analysis (FEA) for a considered structural problem including its post-processing. The model shall be specifically developed to capture major expected outputs (e.g., strain concentrations in the vicinity of damage tips). Also, FEA mesh density shall be correlated, at least, qualitatively with expected strain or displacement gradients. The second effort is completely independent mechanical testing including DIC-based characterization of strain and displacement fields. Although these efforts seem to be standard computational and experimental exercises, their robust statistical comparison is a major challenge primarily due to inevitable a) statistical variability of measurements; b) differences in locations of considered points (i.e., between nodes in FEA and speckles in testing); and c) potential non-uniqueness of interpolations, especially (Gurvich, 2013c), in analysis of random strains. The third effort, therefore, is addressing probabilistic test/model integration including 1) selection of evaluation criteria (e.g., as a normalized gap between FEA and DIC); 2) its statistical treatment with
