PHOTOGRAPHIC SENSITIVITY: A COLLOID
CHEMICAL PROBLEM.[†]

By S. E. Sheppard.

IN A paper presented at the Colloid Symposium at Madison in 1923, the author discussed one important factor affecting photographic sensitivity. This is grain-size, or dispersity of the silver halide, and the distribution of grain-sizes in one and the same emulsion. It was shown then that in one and the same emulsion sensitivity increases statistically with the size of grain in the sense that the chance of a grain being made developable by a given exposure increases with the size (projective area). Other factors intervene, however, as between one emulsion and another, so that average grain-size is not the sole factor conditioning sensitivity.

It was found several years ago by Lüppo-Cramer that the sensitivity of plates could be greatly diminished by treatment before exposure with chromic acid, followed by thorough washing to remove the chromic acid. This desensitizing reaction has been quantitatively investigated in recent years both in England and in this country, and the results of the work are discussed in this paper. It is concluded that high photographic sensitivity is connected with something other than silver halide which is formed in the grains. Experiments by the author are described which show that emulsions made in the same manner, and having the same grain-size properties, can have quite different photographic sensitivities and properties according to the gelatin used. Hence, it is concluded that the substance in question is specifically afforded by the gelatin.
