tion. Static glands are dimensioned to provide the O-ring seal with an ideal 25% squeeze. The glands for reciprocating seals are dimensioned for minimum O-ring squeeze to minimize static and dynamic friction. Rotary seal applications incorporate female glands dimensioned to provide peripheral compression for the O-ring seal. Each of these cases is discussed fully under the specific application of static and dynamic seals (Chaps. 4 to 6). Such physical parameters as O-ring size and the temperature and pressure incurred by the O-ring will help to determine the gland dimensions; these parameters are discussed in Sec. 11.

3. *Diametral Clearance:* An O-ring seals the leak path between two concentric parts (i.e., a piston within a cylinder bore). The O-ring must block the maximum gap between the two parts without extruding. The maximum gap is the difference between the diameters of the parts—the diametral clearance between the pistons and the bore. It is based on the fact that the piston may be forced to one side of the cylinder bore, producing a gap twice that of the radial difference. If the piston is held concentric in the bore by bearings or other means, the radial clearance may be used as the maximum gap. The differential pressure across the O-ring seal and the hardness of the O-ring seal limit the maximum diametral clearance allowable. Figure 5 presents the maximum gap allowed given the O-ring hardness and the fluid pressure across the O-ring seal. These extrusion curves are very conservative for most O-ring applications, since they are based on 100,000 pressure cycles, each cycle increasing from zero to the indicated pressure at the rate of one cycle per second at a test temperature of 160°F. Because the extrusion curves are conservative and machining costs are greater for closer tolerances and smaller-diameter clearances, the maximum gap is usually recommended for
