LESFOIL:

Large Eddy Simulation of Flow Around a High Lift Airfoil Lars Davidson, Davor Cokljat, Jochen Fröhlich, Michael A.

Leschziner, Chris Mellen, Wolfgang Rodi, 2012-09-22 Large Eddy Simulation is a relatively new and still evolving computational strategy for predicting turbulent flows. It is now widely used in research to elucidate fundamental interactions in physics of turbulence to predict phenomena which are closely linked to the unsteady features of turbulence and to create data bases against which statistical closure models can be assessed. However, its applicability to complex industrial flows to which statistical models are applied routinely has not been established with any degree of confidence. There is in particular a question mark against the prospect of LES becoming an economically tenable alternative to Reynolds averaged Navier-Stokes methods at practically high Reynolds numbers and in complex geometries. Aerospace flows pose particularly challenging problems to LES because of the high Reynolds numbers involved, the need to resolve accurately small scale features in the thin and often transitional boundary layers developing on aerodynamic surfaces. When the flow also contains a separated region due to high incidence, say the range and disparity of the influential scales to be resolved is enormous and this substantially aggravates the problems of resolution and cost. It is just this combination of circumstances that has been at the heart of the project LESFOIL to which this book is devoted. The project combined the efforts, resources and expertise of 9 partner organisations: 4 universities, 3 industrial companies and 2 research institutes.

Recent Results in Laminar-Turbulent Transition Siegfried Wagner, Markus Kloker, Ulrich Rist, 2004 Methodical investigations of laminar-turbulent transition in wall-bounded shear flows under controlled conditions are essential for untangling the various complex phenomena of the transition process occurring in flows at practical conditions. They allow understanding of the instability processes of the laminar flow and thus enable the development of tools for flow control. On the one hand, the laminar flow regime can be extended by delaying transition to reduce viscous drag, and on the other hand, large scale flow disturbances or transition can be forced in order to enhance momentum and mass exchange. Thus, flow separation can be prevented or mixing of fuel and air in combustion engines enhanced, for instance. The DFG Verbund-Schwerpunktprogramm Transition, a cooperative priority research program of universities, research establishments and industry in Germany, has been launched in April 1996 with the aim to explore transition by a coordinated use, development and validation of advanced experimental techniques and theoretical numerical simulation methods, binding together all the appropriate resources available in Germany. At the very beginning of the six-year research period, specifically selected test problems were to be investigated by various theoretical and experimental methods to identify and possibly rule out inadequate numerical or experimental

methods With respect to experiments it was planned to use multi sensor surface measuring techniques the infrared measuring technique and particle image velocimetry PIV in addition to hot wire techniques to get instantaneous images of flows in sections on surfaces or within the complete flow field
