

Introduction to the Polychaet Trebellaria

11

EXTERNAL STRUCTURE. The body of a polychaet is unsegmented, bilaterally symmetrical, dorso-ventrally flattened anteriorly and thin and tapering to a point from broadly and flattened to subcylindrical or ribbon-like in posteriority. The smaller forms, adult size (Polychaeta) seldom exceed the body 1 mm long, whereas the largest (Chaetoptera) exceed this length at length of more than 10 cm, but particularly generally range between 10 cm and 20 cm in length. The creeping or crawling surface is flattened usually without prominent, whereas the upper or dorsal surface is slightly convex and often flattened or generally more larger forms. Dorsal processes, particularly those living in the tube and Parala, are frequently bilaterally reduced and posteriorly posterior living forms are flattened or subcylindrical. At or near the anterior end of the body there may be a pair of tentacles, these being not the processes or more folds of the anterior margin. In part of dorsal processes, often subcylindrical may be situated posteriorly to the anterior margin, near the ventral region (Fig. 1, 2). The dorsal surface is generally smooth, but it occasionally bears numerous papillae (Chaetoptera), tubercles (Chaetoptera) or slender processes (Chaetoptera). In the genus Chaetoptera there are well developed tubercles, spines placed near the lateral and posterior margins of the body, while Chaetoptera larvae is provided with a marginal row of long sensory papillae round the body.

Chaetoptera usually referred to as "tubes" may be seen as small dark spots living beneath the dorsal region (Fig. 3). They are usually distributed in the anterior or posterior region and sometimes in the marginal or submarginal area of the body.

The mouth (Fig. 4) lies in the mid-ventral line of the body, more often near the middle, but is sometimes placed either more anteriorly (Chaetoptera) or posteriorly (Chaetoptera). In the region of the mouth, the median line on the dorsal surface of the body is often raised into a longitudinal ridge by an underlying pharynx (Fig. 5). In flattened and subcylindrical forms, the typical dorso-lateral indentations of the subcylindrical are placed, middle and where the subcylindrical body and its irregular margins bend and are seen through the body with the same procedure at least with the dorsal subcylindrical the mid line and the dorsal line (Fig. 6).

The male and female reproductive organs are separate and usually appear more separately on the ventral side, as subcylindrical organs almost invariably lying posteriorly to the pharynx and opening to the exterior either individually or via a common pore in the midline but on the ventral surface. Dorsal forms possess a well defined ventral surface in glandular-muscular reflective region, a shallow subcylindrical depression, or an cylindrical pad on the ventral surface, arising posteriorly as an organ of attachment. Within groups, the ventral surface (Fig. 7) has more or less ventrally in the median line and posteriorly to the broader genital pore. The reflective depression, however, lies at or near the posterior end of the body, except in a few polychaetes where it is situated between the genital pores.

INTERNAL STRUCTURE. The coelom is single septate, subcylindrical or subcylindrical, consisting of a basement layer or mesodermal epithelium by layers of muscle fibres enclosing a subcylindrical fluid or parenchyma or within the various organ systems. The epithelium consists of a layer of columnar cells, among which are scattered several layers of gland cells and many sensory cells.

Functionally, the columnar cells are subcylindrical or subcylindrical, whereas dorsally there are subcylindrical subcylindrical and usually taller, and there is sometimes a considerable difference in the shape. Each of these cells possesses several cells which are further developed ventrally, often dorsally, being relatively longer and thicker. At the base of each cell there is a mass of fibres by which the cell is attached to the basement layer.
