At absolute thermodynamic equilibrium, a given macroscopic system rests in a structureless and time-independent state. It can be brought out of equilibrium in several ways. A first possibility is to prepare the system in a metastable state and to let the stable phase nucleate. This is the case of an undercooled liquid that solidifies as soon as a sufficiently large germ is present; at a given temperature the solid phase is more stable than the liquid phase and the fraction of the solid phase spontaneously increases, separated from the remaining liquid by a solidification front. In the same way, after ignition by a spark, a mixture of fresh gases releases its chemical potential energy by burning; a flame front propagates from burned towards unburned regions. Propagation of a front is the simplest way to restore uniformity at the expense of a metastable state. Questions of interest then relate to the propagation velocity and the morphology of the front, either unmodulated or modulated, and further, either cellular or irregular, i.e. e.g. dendritic (solidification) or turbulent (flame). It is important to realize that in such cases, the system can be assumed to be closed in the thermodynamic sense, but if it is actually closed, the propagation will stop after a while. In a conveniently designed open system, this kind of propagation of a front in a *multi-phase* medium can be maintained indefinitely. These topics form the basis of the first part of our workshop.

A second possibility is to consider *homogeneous* open systems driven far from equilibrium, by imposed gradients of intensive quantities: pressure, temperature, chemical potential. Along the thermodynamic branch, the response of the system in terms of fluxes of extensive quantities will display the same spatio-temporal symmetries as the excitation. However, the system can choose other solutions breaking these symmetries. Patterns —dissipative structures— can form, made of different types of cells, either steady or time dependent depending on the mechanisms involved.

Over the last few years, questions of interest have been mainly related, on one hand, to the predictability problem in systems with frozen spatial degrees of freedom and, on the other hand, to detailed properties of the patterns space dependence (wavelength selection) in weakly confined systems. In this last domain the most impressive results concern the unfolding of space and time dependence in the vicinity of a supercritical bifurcation to steady rolls typified by the Rayleigh-Bénard problem. In this case propagation phenomena enter the picture only at the
