

Quartz Cementation

Two phases of cementation - This is a quartz sandstone, seen under plain light. The quartz grains have quartz overgrowths (labeled 'o'), reflecting a first phase of cementation, and then, later, a period of carbonate cementation (c) seen as a brownish material filling the pore space.

Quartz Cementation In Sandstones:

Quartz Cementation in Sandstones R. Worden, Sadoon Morad, 2009-09-18 Quartz is the major porosity reducing cement in many sandstone sequences. Therefore Quartz cements represent a key source of petrographic and geochemical information about diagenetic history. They are also the major determinant of sandstone reservoir quality. While the ultimate goal of research in this area is to make robust predictions about the amount and distribution of quartz cements in a wide variety of depositional and burial settings, there are nevertheless large areas of the subject that are poorly understood and remain the subject of controversy. The aim of this Volume, which is based partly on papers submitted to a 1996 workshop in Belfast and partly on invited contributions, is to bring together some of the main strands of research into quartz cements and provide a focus for debate and direction for future research. This book will be welcomed by sedimentologists, petrographers and geochemists involved in sandstone diagenesis as well as by petroleum geologists seeking a deeper understanding of the factors influencing reservoir porosity and permeability. Contributors from 11 countries and 4 continents. Represents the benchmark in quartz cement research. If you are a member of the International Association of Sedimentologists for purchasing details please see <http://www.iasnet.org/publications/details.asp?code=SP29>

Does Oil Emplacement Stop Diagenesis and Quartz Cementation in Deeply Buried Sandstone Reservoirs Mohammed Bukar, 2013 Reservoir quality relates to the presence of porosity and the connectivity of the pores of the reservoir rock, which controls permeability. Deeply buried sandstones in sedimentary basins lose their reservoir quality due to compaction and cementation. Quartz cement is the most volumetrically important porosity occluding cement in sandstones buried to depths greater than about 3000m. Precipitation of quartz cement requires a source of silica transportation of the silica in solution from source to the point of precipitation and clean grain surfaces to grow on. For these

processes to take place water is required to dissolve the mineral grains that provide the source of silica to provide aqueous fluid pathway from the site of mineral dissolution to the site of precipitation and water is required at the site of mineral precipitation to enable mineral growth In oil or gas fields displacing the aqueous pore fluid by petroleum disrupts the pathway between the reactants and points of precipitation If the oil saturation becomes high i the residual irreducible water becomes isolated within a continuous hydrocarbon phase or ii the aqueous pathway becomes tortuous and diffusion becomes slow or iii grain surfaces become coated by oil if the sandstone is oil wet However over the years a controversy has developed as to whether oil emplacement into reservoir stops quartz cementation and preserves porosity at depth The research presented in this thesis used core samples wireline logs and well reports collected from the oil and water legs and the transition zone of Upper Jurassic marine sandstones of the Ula and Tambar fields from the Norwegian North Sea They were studied using a range of techniques core analysis core logging downhole wireline analysis optical microscopy scanning electron microscope SEM cathodoluminescence CL X ray diffraction XRD fluid inclusion UV petrology and thermometry The distributions of all potential controls on porosity and permeability have been quantified so that it has been possible to assess the influence of all possible controls on quartz cement as well as fluid type Thus the roles of depositional facies grain size sorting chlorite coats and microcrystalline quartz coats have all been assessed The main diagenetic cements in both Ula and Tambar fields are quartz overgrowths grain coating microcrystalline quartz K feldspar cement illite dolomite and minor amounts of calcite and chlorite Fluid inclusion evidence shows that quartz cementation was probably a continuous process and is still taking place in both fields Quartz cementation occurred in the presence of some oil as shown by the presence of oil inclusions within quartz cement in both Ula and Tambar However there are far fewer oil inclusions in quartz cement in Tambar than Ula suggesting that oil emplacement occurred later in Tambar than Ula There is less quartz cement in the coarser grained sandstones in the oil legs than the water legs of Ula and Tambar suggesting that quartz cementation has been inhibited in these facies by the addition of oil Finer grained facies in both fields have more grain coating microcrystalline quartz that has effectively inhibited quartz cementation in both oil and water legs Stable isotope data show that the carbonate cements in the oil leg grew at relatively lower temperatures than those in the water legs Precipitation temperature for carbonate cement in the oil leg stopped at the time of oil emplacement but carbonate cements in the water leg carried on growing or recrystallising at higher temperatures and show progressive input of source rock derived CO₂ as the carbon isotopes get progressively lighter in both Ula and Tambar fields Reservoir quality in the Ula field is primarily controlled by a combination of depositional facies mechanical compaction and early oil emplacement and locally by facies controlled microcrystalline quartz In the Tambar field early formed grain coating microcrystalline quartz mainly controls the reservoir quality and effects of oil emplacement are not as significant as in Ula due to the later oil charge The results of this work have academic and economic significance Understanding the controls on reservoir quality and the effect of oil

emplacement on quartz cementation may be used 1 as analogues in other basins of known petroleum charge history 2 to improve appropriate reserve calculation and well planning during the appraisal stage and 3 to assist in reliable prediction of aquifer performance during production and lead to proper decision on number and positions of injection wells during the later life of the field

Application of Cathodoluminescence Imaging to the Study of Sedimentary Rocks Sam Boggs, David Krinsley, 2006-09-21 Minerals in sedimentary rocks emit characteristic visible luminescence called cathodoluminescence CL when bombarded by high energy electrons CL emissions can be displayed as colour images in a cathodoluminescence microscope or as high resolution monochromatic images in a scanning electron microscope This provides information not available by other techniques on the provenance of the mineral grains in sedimentary rocks and insights into diagenetic changes The book first published in 2006 begins with an easily understood presentation of the fundamental principles of CL imaging This is followed by a description and discussion of the instruments used in CL imaging and a detailed account of its applications to the study of sedimentary rocks The volume is a comprehensive easily understood description of the applications of cathodoluminescence imaging to the study of sedimentary rocks It will be an important resource for academic researchers industry professionals and advanced graduate students in sedimentary geology

Cathodoluminescence of Quartz and Its Application to Sandstone Petrology Ulf Zinkernagel, 1978 [The Relationship Between Damage and Localization](#)

Helen Lewis, G. D. Couples, 2007 The many kinds of porous geomaterials rocks soils concrete etc exhibit a range of responses when undergoing inelastic deformation In doing so they commonly develop well ordered fabric elements forming fractures shear bands and compaction bands so creating the planar fabrics that are regarded as localization Because these induced localization fabrics alter the bulk material properties such as permeability acoustic characteristics and strength it is important to understand how and why localization occurs and how it relates to its setting The concept of damage in several uses describes both the precursor to localization and the context within which it occurs A key theme is that geomaterials display a strong material evolution during deformation revealing a close linkage between the damage and localization processes This volume assembles perspectives from a number of disciplines including soil mechanics rock mechanics structural geology seismic anisotropy and reservoir engineering The papers range from theoretical to observational and include contributions showing how the deformed geomaterial's emergent bulk characteristics like permeability and seismic anisotropy can be predicted

Reservoir Quality of Clastic and Carbonate Rocks P.J. Armitage, A.R. Butcher, J.M. Churchill, A.E. Csoma, C. Hollis, R.H. Lander, J.E. Omma, R.H. Worden, 2018-06-18

Reservoir quality is studied using a wide range of similar techniques in both sandstones and carbonates Sandstone and carbonate reservoir quality both benefit from the study of modern analogues and experiments but modelling approaches are currently quite different for these two types of reservoirs There are many common controls on sandstone and carbonate reservoir quality but also distinct differences due primarily to mineralogy Numerous controversies remain including the question of oil inhibition the key control on pressure solution and geochemical flux of material to or from reservoirs This collection of papers contains case study based examples of sandstone and carbonate reservoir quality prediction as well as modern analogue outcrop analogue modelling and
