Abstract

Over the past several years, NiTi alloys have seen an increased use in medical devices where components are compressed to catheter dimensions, delivered through tortuous anatomy and deployed in various diseased locations within the human body. Nitinol is well suited to the design constraints imposed by such conditions, however, only modest progress has so far been made regarding long term predictions of the structural integrity of such components. Challenges in predicting long term reliability of superelastic NiTi medical components include the consequences of manufacturing tolerances, uncertainty with regard to in vivo loading and the inherent complexity of superelastic material behavior. In this article, we focus on the latter challenge and discuss ongoing research to characterize the effects of phase transformation and accurately obtain calibrated material constitutive relations for polycrystalline Nitinol materials. Our approach involves a combination of full-field strain measurements using phase shifted Moiré interferometry and the development of improved finite element methodology to account for various material behaviors and simulated conditions. Phase shifted Moiré interferometry provides unprecedented accuracy in the measurement of strains and displacements in the vicinity of stress risers such as notches and can be used to guide and verify finite element models for implantable superelastic devices.

Introduction

Nitinol has become a material of importance in medical applications as it allows designers to overcome a wide range of issues related to the miniaturization of medical devices and the increasing trend for less invasive, and therefore less traumatic procedures across medical specialties. Applications using Nitinol include self-expanding stents, graft support systems, filters, baskets and various other devices for minimally invasive interventional and endoscopic procedures. The primary feature responsible for this widespread use is the stress-induced reversible phase transformation responsible for recoverable macroscopic strains of 8% or more and has been the subject of much study over the years.

The use of Nitinol for implantable medical devices is not without its challenges. Intrinsic to the material is a lower fracture toughness and faster crack growth rates than conventional engineering materials [1]. Another challenge is

the measurement of key properties such as elastic moduli which is made difficult by the contributions of stress-induced martensite and martensite reorientation during testing.

In the face of these challenges, Finite Element Analysis (FEA) has proven useful in the design and development process as it allows designers to predict and optimize critical performance parameters, such as force exerted by a stent on a vessel wall, and can correlate design geometry and guide accelerated test methods. Critical to the application of finite element methodology are meaningful material property inputs and confidence in the relationship between the analysis outputs and the real world.

Recently, the availability of constitutive models for Nitinol has improved, but in light of present experimental evidence, interpretation and use of these models requires caution. Here we present a methodology to guide future advancements of theory and practice and the corresponding evidence that suggests the notion that strains in excess of 2 percent may be erroneous, at least at the material level.

Moiré Interferometry

Moiré interferometry is a well established photomechanics technique for characterizing detailed material response [2]. Diffraction gratings are replicated on the sample surface which is then observed in an interferometer as shown schematically in Figure 1, to reveal fringe patterns representing in-plane surface strains for any applied loading condition. Phase shifting is a technique of acquiring and processing fringe patterns that extends conventional interferometric measurements through over-sampling and automated image processing [3].
