Abstract: Applications of nanotechnology in biomedical engineering are vast and span several interdisciplinary areas of nanomedicine, diagnostics, and nanotheranostics. Herein, we provide a brief perspective on nanotechnology as an enabling tool for the design of new functional materials and devices for medical applications. Semiconductor nanocrystals, also known as quantum dots, are commonly used in optical imaging to diagnose diseases such as cancer. Varieties of metal and metal oxide nanoparticles, and two-dimensional carbon-based nanostructures, are prospective therapeutics and may also be used in protective antiviral/antibacterial applications. Similarly, a number of nanomaterials have shown the potential to overcome the drawbacks of conventional antiviral drugs. However, assessing the adverse effects and toxicities of nanoparticles in medicine and therapeutics is becoming more critical. This article discusses the latest developments of nanomaterials in diagnosis, nanotheranostics, and nanomedicines, with particular emphasis on the importance of nanomaterials in fighting against coronavirus disease. Further, we considered the safety and toxicity of nanomaterials in the context of biomedical applications. Finally, we provided our perspective on the future of nanotechnology in emerging biomedical engineering fields.

1 Introduction

Nanotechnology is an enabling tool for designing new materials and devices, which opens a new era of biomedical engineering. Biomedical engineering is an expeditious field that bridges the gap between technology, biology, and medicine. The potential use of nanotechnology in biomedical engineering includes the early detection and treatment of diseases. Cognizance in physical/chemical biology, fabrication principles, and the development of predictive methods to control them, are likely to lead the major advances in nanomedicine and nanodevices.

Paul Ehrlich, a medical doctor who expressed great interest in bacteriology and immunology, proposed the concept of targeted drug delivery that was mediated by nanoparticles in 1954 [1]. He called the delivery system “Zauberkegeln,” which translates to “Magic bullets” in English. This concept gained momentum in 1950–1960 and the controlled release of drugs has since then attracted significant attention. The historical development of nanoparticles (NPs) for biomedical applications over the years is depicted in Figure 1. Professor Peter Paul Speiser and his group first investigated polyacrylic beads for oral administration and developed NPs for drug delivery purposes and vaccines in 1973 [1,2]. Several vaccinations, such as those for tetanus and diphtheria, require multiple injections to build up sufficient antibodies for protection. It was anticipated that the sustained release mechanism of NPs would provide constant immune stimulation, and hence, one injection would be sufficient to achieve the necessary antibody response. Within a short time, the Johns Hopkins
