

Reaction Energetics – Lecture 3

- How do differences in free energy and chemical structure impact equilibria, reaction rate
- Reaction coordinate diagram

- Reaction coordinate (x-axis): often about as "extent of reaction" but is most appropriately thought of as a vibrational mode for bond making and formation
- Potential energy (y-axis): amount of work a system can do at constant temperature and pressure
- Example: consider the stretching of Bu-Cl to Bu^+ and Cl^- . Diagrams more complicated as non-linear molecules have degrees of vibrational freedom as the x-axis becomes a $(3N-6)$ -dimensional hypersurface. Instead, we can take a reaction coordinate along a single degree of freedom.

Morse Potential

- A, B, and TS are all stationary points (e.g., minima on a potential energy surface). The TS is a local maxima on the reaction coordinate but a saddle point on the potential energy surface.
For all stationary points: $\frac{\partial E}{\partial r} = 0$
For ground-state structures: $\frac{\partial^2 E}{\partial r^2} > 0$
For the transition state: $\frac{\partial^2 E}{\partial r^2} < 0$
- TS lifetime is extremely short and on the order of a single molecular vibration ($10^{-12} - 10^{-13}$ sec) so it is not present in any appreciable concentration
- TS is an energy while the activated complex (or TS structure) is a structure
- All structures have an associated energy and the position of the equilibrium (K) between those structures/states is related to the difference in free energy between those structures

$$A \xrightleftharpoons{K} B \quad K = \frac{[B]}{[A]} \quad \Delta G = -RT \ln K_{eq} \quad K_{eq} = \frac{[B]}{[A]} = e^{-\Delta G/RT}$$
