

Parts Of A River

Rivers are a vital part of the water cycle on Earth. They carry water that precipitates in the mountains and hills back down to the seas and oceans. River water is freshwater and not salty like the sea. In the mountains, it is often at its cleanest and can sometimes be drunk straight from the river. Not all rivers are filled by rainwater. Some are created by meltwater - water released when glaciers or snow melts high up in the mountains. Along their course, many rivers will merge with each other or branch off in separate directions.

THE SOURCE

The source of a river is always the highest point on its course. Water always naturally flows downhill. Most rivers begin their journey in high places such as mountains or hills. They are often very small trickles at this point. Many rivers have lots of different sources - these are called tributaries. A river can be a tributary for another river. The rivers are narrower and often shallower here. They flow much faster than further downstream.

WATERFALL

Fast flowing rivers can erode soft rock and create waterfalls. Harder rock isn't eroded so the height and shape of a waterfall are determined by where the harder rock is in the landscape. The tallest river-fed waterfall in the world is Angel Falls (379m) in Venezuela.

MEANDERING RIVERS

Rivers follow the path of least resistance. As they flow over the land, they erode the landscape. Eventually, this causes their course to change. Rivers change their course continually.

SAND BARS AND ISLANDS

By the time a river reaches this stage, it isn't powerful enough to carry heavy sediment such as stones. These sink to the bottom and form sand bars or islands.

OXBOW LAKES

Over time, a meandering river may erode a new, shorter path through the landscape. This can cut off what was once a bend in the river creating an oxbow lake.

THE MOUTH

The point where the river meets the ocean or sea is called its mouth. The sediment and silt often forms muddy banks here.
