

# Reproduction and its Hormonal Control

Different mammals have different patterns of reproduction:

- Eg mammals, rats and mice can breed all year round, whereas others have distinct **breeding seasons**. This is to ensure that the young are born when food is abundant. The timing of the breeding season is regulated by a **biological clock**, which is probably adjusted by seasonal changes in day length.

In mammals the **gametes (sex cells)** are:

- small motile male gametes (sperm) which is produced in large quantities
- larger, non-motile food storing female gamete (ovum) which is produced in much smaller numbers

**Gametogenesis** is the formation of gametes:

- sperm production is called **spermatogenesis**
- where the eggs are formed (matured) is called **oogenesis**

In the females of all mammals, there is a cycle known as:

- **Oestrous cycle** → ovulation, when the female is most fertile
- **Menstruation cycle** → the uterus lining in all mammals undergoes a similar pattern of thickening during a reproductive cycle. However if fertilisation does not occur, the uterine lining of primates breaks down and it is discharged with blood through the vagina, whereas the uterine lining of non-menstruating mammals is reabsorbed and there is no excessive bleeding. The discharge of blood is called menstruation.
