NATURAL HISTORY OF THE AMERICAN LOBSTER.

By FRANCIS WILSON BENDIRE, JR., D. D., M. D.,
Professor of Biology, Western Union University, Cincinnati, Ohio.

Chapter I.—THE LOBSTERS AND ALLIED CRUSTACEA, THEIR ZOOLOGICAL RELATIONS, HABITS, DEVELOPMENT, AND USE AS FOOD.

NATURAL HISTORY OF THE CRUSTACEA.

Nature works according to definite principles, and with a degree of uniformity which for most of our purposes is practically absolute. Accordingly we find that whenever an animal or plant has been successfully domesticated or otherwise the young of any kind have been successfully reared by the artificial insemination and subsequent care of the eggs, as in the case of the silkworm or the chickadee, this has been accomplished by seeing, whether intelligently or not, to conform with the principles of nature. The student of the crustacean is made to yield to experiments which a knowledge of its habits and structure would suggest. In the lobster we have to deal with another and distinct type, for although this animal exists in the sea, it is not a fish, but an arthropod, and a knowledge of the ways of fishes and mollusks will help but little in the study of its habits or in the propagation of its race.

The following paragraphs on the general characteristics of the arthropods will be of little or no use to professional zoologists, but may help to set our subject in a clearer light for other readers.

Of the signs of more animal types recognized by zoologists the arthropods are distinguished by their complicated structure and wonderful diversity of form. In the wide range and specialization of their members, they show exceptional facilities and corresponding activity. In the latter respect, at least, some of the insects are not surpassed by birds, the most active vertebrates.

The body of the arthropod is composed of a series of successive segments, the segments or somites, which in conformity to systematic anatomy are divided into three groups, pertaining to the head, thorax, and abdomen. (Pl. I, figs. 1 and 2.) Temporally, each segment at one time possessed a pair of jointed limbs, and some of the segments still retain them. In the living adult state, the body is normally maintained in a definite upright position, which is also one of variable condition, whether the animal is in motion or at rest. These characteristics are shared in some degree by the annelid
