

computer screen, one of which was associated with a fixed-time (FT) schedule and the other with a progressive-time (PT) schedule. Neither schedule required a response; the reinforcers were simply delivered at the end of the scheduled time period. After each successive reinforcer, subjects selected one or the other schedule, which then remained in effect throughout that trial. If a subject initially selected the stimulus associated with the PT schedule, a point was delivered immediately (0 s), and each successive choice of the PT schedule gradually increased the time to point delivery in fixed increments. If a subject initially selected the stimulus associated with the FT schedule, a point was delivered after 60 s and the PT schedule was reset to 0 s.

Subjects were given the same set of instructions throughout the experiment. Under the first experimental condition, the instructions accurately characterized the sequence of PT and FT choices that would produce the most reinforcement (i.e., the schedule and the instructions were identical). The size of the increments (step size) in the PT schedule was altered gradually across successive experimental conditions (in ascending and then descending order), such that the same instructions gradually became less (and then more) accurate in describing the optimal choice sequence. This unique procedure permitted examination of the transition from instructional to schedule control on a continuum of changing stimulus conditions, and examination of schedule control as a function of history.

Instructional control was established quickly in the first condition, in which instructions accurately described the schedules. However, conformity with instructions necessarily constrained the range of behavior (choice patterns), thereby both precluding contact with changes in the schedule and reducing subsequent control of responding. Choices continued to be controlled by in-

structions as the PT step size increased across several experimental conditions. As the instructions became progressively more inaccurate, however, choice patterns became more variable and produced more reinforcement, resulting in an abrupt transition from instructional to schedule control. The extent to which choices were controlled by the schedule contingencies as PT step sizes decreased (in the descending sequence) varied according to the point at which instructional control first broke down in the ascending sequence, suggesting that the history of consequences for following inaccurate instructions can have enduring effects on behavior.

The schedules in Hackenberg and Joker's (1994) experiment are analogous to many situations in the natural environment in which conditions gradually change (e.g., the progression of an illness, potency of a drug, the economy) such that instructions from others (e.g., physicians, financial advisers) that initially described the schedule become progressively less accurate. Hackenberg and Joker's results suggest that the history and degree of correspondence between instructions and consequences of behavior may affect the extent to which choices are determined by those changing conditions or continue to be controlled by instructions. In some situations, instructional control and weak control by changing schedule conditions are desirable because they increase the probability that a response will persist despite short-term punishers, extinction, or increasing work requirements (e.g., a physician's instructions when a medical program takes time to work). In other situations, control by instructions is maladaptive (albeit not always for the person giving them). Scam artists, for example, strengthen instructional control by initially arranging consequences that support their instructions (such as ensuring that the victim receives "profits" for a period of time) so that instructions will continue to control escalated investments in a
