Computing Qualitatively Correct Approximations of Balance Laws Laurent Gosse, 2013-03-30 Substantial effort has been drawn for years onto the development of possibly high order numerical techniques for the scalar homogeneous conservation law an equation which is strongly dissipative in L1 thanks to shock wave formation Such a dissipation property is generally lost when considering hyperbolic systems of conservation laws or simply inhomogeneous scalar balance laws involving accretive or space dependent source terms because of complex wave interactions An overall weaker dissipation can reveal intrinsic numerical weaknesses through specific nonlinear mechanisms Hugoniot curves being deformed by local averaging steps in Godunov type schemes low order errors propagating along expanding characteristics after having hit a discontinuity exponential amplification of truncation errors in the presence of accretive source terms This book aims at presenting rigorous derivations of different sometimes called well balanced numerical schemes which succeed in reconciling high accuracy with a stronger robustness even in the aforementioned accretive contexts It is divided into two parts one dealing with hyperbolic systems of

balance laws such as arising from quasi one dimensional nozzle flow computations multiphase WKB approximation of linear Schrödinger equations or gravitational Navier Stokes systems Stability results for viscosity solutions of onedimensional balance laws are sketched The other being entirely devoted to the treatment of weakly nonlinear kinetic equations in the discrete ordinate approximation such as the ones of radiative transfer chemotaxis dynamics semiconductor conduction spray dynamics or linearized Boltzmann models Caseology is one of the main techniques used in these derivations Lagrangian techniques for filtration equations are evoked too Two dimensional methods are studied in the context of non degenerate semiconductor models

Equations Songting Luo,2009 Crandall and Lions 23 introduced the concept of viscosity solutions which provides a foundation for studying the Hamilton Jacobi equations both theoretically and numerically Ever since then computing the viscosity solutions numerically has become very important in a variety of applications A lot of numerical methods have been developed to compute the viscosity solutions We study the convergence of classical monotone upwind schemes for example the fast sweeping method for static convex Hamilton Jacobi equations by analyzing a contraction property of such schemes Heuristic error estimate is discussed and the convergence proof through the Hopf formula in control theory is also studied

Monotone upwind schemes are at most first order [51]. In order to improve the accuracy when there is source singularity we introduce a new fast sweeping method for the factored Eikonal equation which improves the accuracy of original fast sweeping method on the Eikonal equation by resolving the source singularity with an underlying correction function. This new factorization idea comes from problems in geosciences. And it provides a possible procedure for source singularity resolution in other problems. Furthermore high order schemes are also important in many applications for example the high frequency wave propagation. The ENO or WENO technique seems to be the popular one. But methods based on ENO or WENO are often slower to converge. They are based on direction by direction approximations with wide stencils to capture smoother approximations of second derivatives. We develop a compact upwind second order scheme for the Eikonal equations by observing a superconvergence phenomena of classical monotone upwind schemes: the numerical gradient of such first order schemes is also first order. The new second order scheme combines this phenomena with the Lagrangian structure of the equations. The stencil can be reduced and it is upwind. As an application of the fast sweeping method we apply the method in computer vision by introducing a distance ordered homotopic thinning algorithm for computing the skeleton of an object represented by point clouds. This algorithm uses the closest point information calculated efficiently by the fast sweeping method. Further possible ideas on developing fast sweeping methods for static non convex Hamilton Jacobi equations are also discussed in the conclusion.
