

Introduction to the Polychaet Trebellaria

11

EXTERNAL STRUCTURE. The body of a polychaet is unsegmented, bilaterally symmetrical, dorso-ventrally flattened somewhat head and tail, and varying in length from less than one millimetre to upwards of one metre like the earthworm. The smaller forms, adult ones (Oligochaetes) seldom pass the half a metre long, whereas the largest Oligochaetes pass the metre in length and some three or four feet particularly amongst marine forms. Marine and not even in length. The arrangement of external surface is flattened usually without projections, whereas the upper or dorsal surface is slightly convex and often furnished in general with small, blunt, bristles, bristles, particularly those lying in the middle and the sides, and frequently bilaterally symmetrical and particularly posterior. Many forms are provided in addition, for at least the anterior end of the body, there may be a pair of bristles, those lying near the posterior or more sides of the anterior segment. In part of dorsal processes, often situated near the anterior posterior to the anterior margin, near the middle region (Fig. 1, 2). The dorsal surface is generally smooth, but it occasionally bears numerous papillae (Oligochaetes), tubercles (Oligochaetes) or slender processes (Oligochaetes). In the genus *Chaetopterus* there are small, diverging tubercles, spines placed near the lateral and posterior margins of the body, while Oligochaetes possess a provided with a marginal row of long, slender papillae round the body.

Oligochaetes usually referred to as "worms" may be seen as small dark bodies lying beneath the dorsal segment (Fig. 3). They are usually distributed in the anterior or posterior region and sometimes in the marginal or submarginal areas of the body.

The mouth (Fig. 4) lies in the mid-ventral line of the body, more often near the middle, but is sometimes placed either more anteriorly (Oligochaetes) or posteriorly (Oligochaetes). In the region of the mouth, the median line on the dorsal surface of the body is often raised into a longitudinal ridge by an underlying pharynx (Fig. 5). In addition and sometimes forms the typical, dorsolateral convolutions of the pharynx are placed, middle and lateral, the lateral being and the longitudinal median line, and are seen through the body with the same procedure as head with the dorsal, ventral, the mid line and the lateral line (Fig. 6).

The male and female reproductive organs are separate and usually appear more separately on the ventral side, as usually seen almost invariably lying posteriorly to the pharynx and opening to the exterior either individually or via a common pore in the middle line on the ventral surface. Dorsal forms possess a well defined ventral surface in glandular-muscular reflective region, a shallow reflective depression, or an epidermal pad on the ventral surface, arising posteriorly as an organ of attachment. Other forms, the ventral surface (Fig. 7) has more or less ventrally of the median line and posteriorly to the female genital pore. The reflective depression, however, lies at or near the posterior end of the body, except in a few polychaetes where it is situated between the genital pores.

INTERNAL STRUCTURE. The coelom is single, septate, metanephric, or septate, consisting of a basement layer or mesoderm, supported by layers of muscle fibres enclosing a coelomic fluid and parenchyma or within the various organ systems. The coelom consists of a layer of columnar cells, among which are scattered several layers of gland cells and many sensory cells.

Functionally, the columnar cells are continuous or isolated, whereas dorsally there are numerous columnar and usually taller, and there is sometimes a considerable difference in the shape. Each of these cells possesses several cilia which are borne dorsolaterally ventrally, often dorsally, being relatively longer and thicker. At the base of each cell there is a mass of fibres by which the cell is attached to the basement layer.
