

deep and seldom exceeded depths of 1.8 m (5 ft). Salinity and depth were found to fluctuate rapidly within an individual pothole both seasonally and annually in response to inflow and outflow. Retention of water in the potholes ranged from a few days following spring thaw to a more or less permanent state. In these regions the potholes are an important source of water supply for livestock and are among the best wetland habitats for waterfowl breeding.

Table 4 presents the concentration of the principal dissolved constituents of some of the typical waters as found by Sloan (1970). The dissolved solids concentration was found to range from very fresh waters to brines that were several times more concentrated than seawater. The fresh waters are dominated by Ca^{2+} and HCO_3^- , brackish waters by Mg^{2+} and SO_4^{2-} , and saline waters by Na^+ and SO_4^{2-} .

Small ponds on the southern Great Plains were investigated by Toetz (1967). These ponds are widely used for livestock watering. In the 29 ponds studied, the mean annual concentration of dissolved solids ranged from 87 to 359 mg/liter and averaged 174 mg/liter. Seasonal variations were also observed. Spring rainfall caused a decrease in concentration, followed by a sharp increase in July. Subsequent evaporation apparently caused continued increases in the dissolved constituents. Although the principal constituents in the water were not measured, the reported mean annual pH and alkalinity values for individual ponds suggested important chemical differences.

Playa lakes are found in essentially barren and flat regions that are also generally dry and undrained. They may contain water of shallow depth for short periods of time and many are salty. Studies of 41 playa lakes typical of those that eventually collect most of the runoff from the high plains of Texas were made by Wells *et al.* (1970). Complete analyses for the principal dissolved constituents were not made; estimates, however, could be made for most of the lakes. These showed that the dissolved solids concentrations were mostly below 300 mg/liter during much of the year. Wide exceptions were recorded; for example,
