Schmid, 2019-03-18 No detailed description available for Marine Algae Marine Algal Colonization on the Monterey Peninsula, California Richard D. Northcraft, 1948 Algae were removed from vertical sloping and horizontal rock surfaces in the intertidal zone of the Monterey Peninsula The surfaces at the vertical station were cleared in January April July and October to study the effect of the seasons of the year on colonization The time of appearance and disappearance of each colonizing alga was recorded as well as its location in the cleared area Also fertility studies of the four commonest species were made at monthly intervals to see to what degree reproduction was correlated with colonization Four types of colonizing algae were distinguished 1 Algae of relatively rapid growth often of transient appearance 2 Perennial algae which appear early and grow rapidly 3 Perennial algae which appear later and grow more slowly 4 Algae which have not colonized in sufficient abundance to be placed with certainty in any of the other categories There is a regular sequence in the colonization of a bare rock surface by marine algae in the intertidal zone on the Monterey Peninsula and the season of the year has little effect in altering their cycle of establishment Certain species such as *Ulva* and *Porphyra* appear to aid the establishment of later colonizing species A large percentage of red algal thalli are in fruit each month of the year Algae which colonize by means of motile spores usually become established on bare rock surfaces more rapidly than species colonizing by means of non motile spores Spores are deposited at random on denuded surfaces and without regard to the normal vertical range of an alga Thalli developing from spores which have become attached above or below the normal vertical range of the species ultimately disappear *An Ecological Characterization of the Central and Northern California Coastal Region: Watersheds and basins* (2 v.) , 1981
