

# Relative motion

- Relative motion is the concept of how the position of one object changes from the perspective of another moving object
- It's crucial to understand that motion is always measured relative to something else
- Common examples include observing a moving train from a stationary platform or another train
- The formula to determine relative velocity is  $V_{AB} = V_A - V_B$ , illustrating how velocities differ depending on the observer's frame of reference

## Practical example: Automobiles

- Relative motion is a key concept in physics that explains how the speed and direction of an object are observed differently depending on the observer's frame of reference
- In the context of automobiles, when you are seated in a moving car, you might perceive that a nearby car is moving slowly if it's traveling in the same direction and speed as yours
- However, to an observer on the sidewalk, both cars may appear to be moving much faster
- Understanding this helps in gauging relative speeds and distances accurately, vital for safe driving and avoiding collisions

*Modern Functional Evaluation Methods for Muscle Strength and Gait Analysis* Andrea Ancillao, 2017-10-24 This book reviews in detail the history of motion analysis including the earliest attempts to capture freeze study and reproduce motion The state of the art technology in use today i e optoelectronic systems is then discussed as motion capture now plays an important role in clinical decisions regarding the diagnosis and treatment of motor pathologies from the perspective of evidence based medicine After reviewing previous experiments the book discusses two modern research projects providing detailed descriptions of the methods used and the challenges that arose in the context of designing the experiments In these projects advanced signal processing and motion capture techniques were employed in

order to design i a protocol for the validation and quality assurance of clinical strength measurements ii an algorithm for interpreting clinical gait analysis data and iii a number of user friendly software tools that can be used in clinical settings to process data and to aggregate the results into reports In closing a thorough discussion of the results is presented from a contextual standpoint

*Initiation and Control of Gait from First Principles: A Mathematically Animated Model of the Foot*  
Craig Nevin, 2010-05-21

This thesis examines the anatomical locations of the dynamic pressures that create the first five footprints when a standing person starts to walk It is hypothesized that the primary activity starts with the dorsiflexion or lifting of the great toe Consequently the metatarsophalangeal region of the forefoot was studied from three directions Viewed side on the great toe free body is found from a detailed post hoc analysis of previous kinematic data obtained from cadavers to operate as a cam The cam model also follows closely from Aristotle's ancient description of the hinged instrument of animate motion Viewed in coronal cross section the first metatarsal torsion strength was estimated in 13 humans 1 gorilla 3 chimpanzees 1 orangutan and 1 baboon set of dry bone specimens of the hands and feet The first metatarsal bone alone contributes 43% of the total strength of all the metatarsal bones A result unique amongst the hominids and apes studied Viewed in horizontal plan the dynamic components and principle axes of the footprints of 54 barefoot humans 32 male 22 female age 32 11 years were studied whilst standing on a 0.5m pressure plate and then immediately when walking over a 2m plate 4 sensors per cm<sup>2</sup> sampled at 100hz Two footprints were obtained during the initial stance posture and the first three footprints of the initial walk Three new principles of animate motion were deduced from the divergent results obtained from complete and dissected cadavers The metatarsal cam from the sagittal side view the ground reaction torque from the frontal coronal view and the amputation artifact The philosophy of experimenting on inanimate cadavers rather than living subjects was intensively researched Instead of assuming that gait is a uniform or regular motion as is usual the foot was analyzed rather as if it was a beam attached to the ground Engineering equations were used to determine the flexural properties of the foot every 0.01 seconds including the principle axes radius of gyration and the local shear stresses on the sensors spaced 5.7mm apart A sequence of these impressions creates a mathematically animated model of the footprint The local force under the foot was normalized against both the total force and contact duration The forces under the foot were each divided between 10 anatomical regions using individual masks for each foot strike Producing a 54 subject database from which the normal behavior of the foot could be quantified The group showed a surprisingly low right foot step off dominance of only 54% The combination of the radius of gyration and impulse in particular produces a succinct but powerful summary of the footprint during dynamic activity The initial angle and magnitudes of the loads that are applied and removed demonstrates that the body first rocks onto the heels after the instruction to walk is given The feet simultaneously invert and their arches rise off the ground as anticipated The principle axes were then animated in a mathematical four dimensional model The horizontal radius of gyration is on average 5 cm during heel strike but increases to 20 cm as the forefoot comes into contact

with the ground finally rising to 25 cm at toe off Significantly the applied load during the fore foot loading phase is more widely distributed than the load being removed A new and unanticipated result that is believed to be a special characteristic of the animate foot The standard deviation of the force under the great toe is the first mechanical parameter to converge in the 54 subjects conclusively verifying the hypothesis that the great toe both initiates and controls gait
