

Chapter 1 of the book contains a number of motivational examples. Chapter 2 summarizes some algebraic background involving Euclidean domains and the algebraic properties of matrices of rational functions. Chapter 3 relates ARMA representations

$$P(\sigma)w = Q(\sigma)\xi,$$

$P(\sigma)$ ,  $Q(\sigma)$  polynomial, and others to first-order behavioural models. Chapter 4 is a study of minimality of the "P" and "DP" models above, and of both "D" (descriptor) models

$$\sigma E \dot{\xi} = A\xi + Bu, \quad y = C\xi + Du$$

and of "DZ" models, which are descriptor models with  $D = 0$ . Chapter 5 studies the relationship between minimal first-order models and polynomial models. Chapter 6 analyses certain structural invariants of first-order models: observability and controllability indices and input-output structure.

In summary, this book is of interest to those seeking a careful unification and analysis of algebraic realization and minimality theory for first-order linear "generalized state-space" representations of dynamical systems.

**The Mathematical Theory of Dilute Gases.** By C. Cercignani, R. Illner, and M. Pulvirenti. Springer-Verlag, New York, 1994. \$49.00, 347 pp., hardcover. ISBN 0-387-94294-7.

As is stated in the introduction, "The idea of introducing a density function  $f(x, v, t)$  to describe the number of particles which at the point  $x$  and at the time  $t$  have the velocity  $v$  is probably due to Maxwell, who gave a heuristic derivation of the distribution function that bears his name. However, it is Boltzmann who in (1872) derived the equation for this distribution."

It turned out to be the right tool to link the microscopic description of the phenomena (at the level of the particles, say molecules or ions or other types of particles) with the macroscopic level (fluids).

The classical macroscopic quantities such as density, momentum, and internal energy are recovered by an integration on the space of velocities, according to the formula

$$\rho = \int f(x, v, t) dv, \quad \rho u = \int v f(x, v, t) dv,$$

$$E = \rho \left( \frac{|u|^2}{2} + \frac{3}{2} \theta \right) = \int |v|^2 f(x, v, t) dv.$$

However, at the level of the Boltzmann equation these quantities cannot be computed via a finite closed system of equations. It is only when the gas becomes dense that it is possible to recover, for instance in some asymptotic regime, the solutions of the classical equations of fluid mechanics.

At least two mathematical difficulties are always present in this program. The first results from the fact that the interaction of molecules is basically nonlinear. The problem remains nonlinear at the level of the Boltzmann equation, which has quadratic nonlinearities, and at the level of the macroscopic equations. The second is the appearance of a notion of "entropy" and "entropy dissipation" which measures how some equations of this program are in some sense "less reversible." Basically, when one follows the path

**The Mathematical Theory of Dilute Gases** Carlo Cercignani, Reinhard Illner, Mario Pulvirenti, 2013-12-01 The idea for this book was conceived by the authors some time in 1988 and a first outline of the manuscript was drawn up during a summer school on mathematical physics held in Ravello in September 1988 where all three of us were present as lecturers or organizers The project was in some sense inherited from our friend Marvin Shinbrot who had planned a book about recent progress for the Boltzmann equation but due to his untimely death in 1987 never got to do it When we drew up the first outline we could not anticipate how long the actual writing would stretch out Our ambitions were high We wanted to cover the modern mathematical theory of the Boltzmann equation with rigorous proofs in a complete and readable volume As the years progressed we withdrew to some degree from this first ambition there was just too much material too scattered sometimes incomplete sometimes not rigorous enough However in the writing process itself the need for the book became ever more apparent The last twenty years have seen an amazing number of significant results in the field many of them published in incomplete form sometimes in obscure places and sometimes without technical details We made it our objective to collect these results classify them and present them as best we could The choice of topics remains of course subjective

especially unfolding theory and classification theory to bifurcation problems Many of the ideas in this part of singularity theory were originally proposed by Rene Thom the subject was then developed rigorously by John Mather and extended by V I Arnold In applying this material to bifurcation problems we were greatly encouraged by how well the mathematical ideas of singularity theory meshed with the questions addressed by bifurcation theory Concerning our title Singularities and Groups in Bifurcation Theory it should be mentioned that the present text is the first volume in a two volume sequence In this volume our emphasis is on singularity theory with group theory playing a subordinate role In Volume II the emphasis will be more balanced Having made these remarks let us set the context for the discussion of the strengths of the singularity theory approach to bifurcation As we use the term bifurcation theory is the study of equations with multiple solutions Nonlinear Partial Differential Equations Helge Holden, Kenneth H. *The Cauchy Problem in Kinetic Theory* Robert T. Glassey, 1996-01-01 This volume studies the basic equations of kinetic theory in all of space. It contains up to date state of the art treatments of initial value problems for the major kinetic equations including the Boltzmann equation from rarefied gas dynamics and the Vlasov-Poisson-Vlasov-Maxwell systems from plasma physics. This is the only existing book to treat Boltzmann type problems and Vlasov type problems together. Although these equations describe very different phenomena they share the same streaming term. The author proves that solutions starting from a given configuration at an initial time exist for all future times by imposing appropriate hypotheses on the initial values in several important cases. He emphasizes those questions that a mathematician would ask first: Is there a solution to this problem? Is it unique? Can it be numerically approximated? The topics treated include the study of the Boltzmann collision operator, the study of the initial value problem for the Boltzmann equation with small and near equilibrium data, global smooth solvability of the initial value problem for the Vlasov-Poisson system with smooth initial data of unrestricted size, conditions under which the initial value problem for the Vlasov-Maxwell system has global in time solutions in both the smooth and weak senses and more.
