

HEALTH CONSEQUENCES OF ALCOHOL ABUSE: OPPORTUNITIES FOR TREATMENT RESEARCH

Alcohol abuse has diverse deleterious effects on health including intoxication, the withdrawal syndrome, and many types of organ damage. The advances in our understanding of how alcohol-related organ damage occurs were reviewed in the IOM report Causes and Consequences of Alcohol Problems (IOM, 1987). This chapter focuses on opportunities for treatment research on alcohol-related illnesses. In terms of mortality, hepatic cirrhosis is probably the most serious alcohol-related disease. In terms of handicapped daily functioning, however, the cognitive impairment induced by alcohol abuse may be more serious. Although advances have been made in treating some alcohol-related illnesses, other disorders have no specific treatment. In general, in the prevention and containment of alcohol-related organ pathology, the paramount concern is to halt the patient's alcohol abuse because abstinence from alcohol in these cases is essential to allow reversibility of organ damage (where possible) and to prevent the progression of cellular and tissue damage.

In considering research approaches to the treatment of alcohol-related health consequences, multisite studies are essential in cases in which the illness occurs with such low frequency that no single site can provide a sufficient number of subjects. Alcoholic hallucinosis, pancreatitis, cardiomyopathy, and certain consequences of cirrhosis of the liver are examples of such disorders. On the other hand, controlled treatment trials for detoxification or for cognitive impairment could be carried out at either single or multiple sites.

INTOXICATION

Work on amethystic agents (agents that reverse intoxication) is in the basic research stage and is not yet ready for treatment evaluation or treatment applications. Likow and Goodwin (1987) have reported that no single drug reverses all the effects of alcohol. Naloxone reverses the depression of the ventilatory response to hypercapnia that is induced by alcohol, but it does not help as a sobering agent. Lithium may attenuate the subjective sense of intoxication. Zimelidine and ibuprofen appear to reduce several types of alcohol-induced cognitive impairment. None of these effects appears to be pronounced, however, and none of these compounds would qualify as an amethystic agent.

Basic research on the effects of alcohol on membrane proteins, especially the calcium and chloride channels, may lead to the development of new drugs that could block the intoxicating effects of alcohol. Because alcohol intoxication is associated with a wide variety of central nervous system effects including ataxia, psychomotor depression, problems of coordination and gait, cognitive impairment, and changes in mood and behavior related to environmental contexts, studies of amethystic agents will have to specify the particular effects of alcohol that are reversed or blocked by the drug. At the present time, certain calcium channel blockers and drugs that serve as partial inverse agonists at the benzodiazepine/GABA_A chloride channel complex offer promising opportunities for future research on amethystic agents. However, this work is not yet ready for formal study in a
