Numerical Simulation Of Oscillatory Convection In Low-Pr Fluids:

Numerical Simulation of Oscillatory Convection in Low-Pr Fluids Bernard Roux, 2013-03-08 For the last ten years there has been an ever increasing awareness that fluid motion and transport processes influenced by buoyancy are of interest in many fields of science and technology. In particular a lot of research has been devoted to the oscillatory behaviour of metallic melts, low Pr fluids, due to the very crucial impact of such flow oscillations on the quality of growing crystals, semiconductors or metallic alloys for advanced technology applications. Test cases on the 2D oscillatory convection in differentially heated cavities containing low Pr fluids have been defined by the organizing committee and proposed to the community in 1987. The GAMM Workshop was attended by 55 scientists from 12 countries in Oct 1988 in Marseille, France. Twenty-eight groups contributed to the mandatory cases coming from France, 12 other European countries, 7 and other countries USA, Japan and Australia, 9. Several groups also presented solutions of various related problems such as accurate determination of the threshold for the onset of oscillations, thermocapillary effect in open cavities and 3D simulations. Period doubling, quasi-periodic behaviour, reverse transition and hysteresis loops have been reported for high Grashof numbers in closed cavities. The workshop was also open to complementary contributions: 5 from experiments and theory, stability and bifurcation analysis. The book contains details about the various methods employed and the specific results obtained by each contributor.

Physical Science Under Microgravity: Experiments on Board the SJ-10 Recoverable Satellite Wenrui Hu, Qi Kang, 2019-10-16 This book presents the physical science experiments in a space microgravity environment conducted on board the SJ-10 recoverable satellite which was launched on April 6th 2016 and recovered on April 18th 2016. The experiments described were selected from 100 proposals from various institutions in China and around the world and have never previously been conducted in the respective fields. They involve fluid physics and materials science and primarily investigate the kinetic properties of matter in a space microgravity environment. The book provides a comprehensive review of these experiments as well as the mission's execution data collection and scientific outcomes.

Convection with Local Thermal Non-Equilibrium and Microfluidic Effects Brian Straughan, 2015-07-08 This book is one of the first devoted to an account of theories of thermal convection which involve local thermal non-equilibrium effects including a concentration on microfluidic effects. The text introduces convection with local thermal non-equilibrium effects in extraordinary detail, making it easy for readers newer to the subject area to understand. This book is unique in the fact that it addresses a large number of convection theories and provides many new results which are not available elsewhere. This book will be useful to researchers from engineering, fluid mechanics and applied mathematics, particularly those interested in microfluidics and porous media.

Numerical Simulations of Fluid Flow and Convection Heat Transfer Through Fluid/porous Layers Baili Zhang,1999

Numerical Simulation of 2-Dlaminar Flow, Heat Generation and Forced Convection from Rectangular Blocks in a Narrow Channel İbrahim Özkol,1992

In this study a directional implicit Computational Fluid Dynamics CFD finite difference code is developed so as to simulate the direct and indirect heat removal through conduction and convection processes from the rectangular blocks attached to the lower surface of a narrow channel geometry Two dimensional unsteady incompressible laminar form of the Navier Stokes N S equations are considered L sing the stream function vorticity approach they are discretized via finite difference technique under the assumption of the Taylor series expansions The discretized equations than reduced to a three banded form of a matrix equality ready to be used conjugate solution formulation In the same manner two dimensional unsteady energy equation discretized with the source term included into three banded matrix form Tw o field equations are solved numerically for various channel rectangular block geometries so as to study the steady state heat transfer characteristics inside channel with possible heat generation inside the blocks It is shown that the numerical model is capable of simulating the main features of the flow field Detailed benchmarks of the present numerical model is attempted so as to validate the devoloped algorithm The streamwise extension

of the recirculation zone behind the rectangular block which is a function of the Reynolds number is very well simulated. Furthermore, it was shown that the heat transfer characteristics of the zone agree well with the experimental and theoretical observations in the literature. Prepared algorithm is a highly stable algorithm but showing slow convergence to a steady state value. Conjugate solution property of the present approach enables one to study complex thermal characteristics of fluid-solid and solid-solid interactions. Beside the classical boundary conditions of the thermal field, the problem domain is further complicated by the presence of discrete heat sources in the rectangular blocks in form of the infinite small heat-generating sheet. Heat generated at various transfer positions are convected by the fluid downstream. The near-wall flow temperature and the Nusselt number distributions over the surface depict the most features of the complex fluid-solid interaction. The steady state temperature inside the blocks and in the substrate are found to be functions of the flow Reynolds number, Prandtl number, heat source position, and substrate bottom surface temperature. Due to the heat generation, the flow is heated well above its inlet value. This causes continuous heat flow from fluid to the lower plate in the recirculating regions of the rectangular blocks and in the cavities where there are more than one obstacle. The present model can simulate the chip-cooling problems for integrated circuit components, i.e., chips on a horizontal printed circuit board which is containing heat-generating rectangular blocks attached to a single layer substrate. Results consistency with other studies which are reported in literature is discussed.

Convection in Coupled Fluid-Porous Media Systems Matthew Mccurdy, 2020. We perform linear and nonlinear stability analyses for thermal convection in a fluid overlying a saturated porous medium in addition to conducting novel numerical simulations. We use a coupled system with the Navier-Stokes equations and Darcy's equation governing the free flow and the porous regions respectively. Incorporating a dynamic pressure term in the Lions interface condition which specifies the normal force balance across the fluid-medium interface permits an energy bound on the typically uncooperative nonlinear advection term, enabling new nonlinear stability results. Within certain regimes, the nonlinear stability thresholds agree closely with the linear ones, and we quantify the differences that exist. We then compare stability thresholds produced by several common variants of the tangential interface conditions using both numerics and asymptotics in the small Darcy number limit. Furthermore, we investigate the transition between full convection and fluid-dominated convection using both numerics and a heuristic theory. This heuristic theory is based on comparing the ratio of the Rayleigh number in each domain to its corresponding critical value, and it is shown to agree well with the numerics regarding how the transition depends on the depth ratio, the Darcy number, and the thermal diffusivity ratio. Finally, we detail the numerical methods used to simulate the coupled system. Our analyses and the heuristic theory are then verified with our numerical results.
