

BODY WEIGHT REGULATION

- The body weight of most individuals tends to be relatively stable over time. Each individual has a biologically predetermined "set point" for body weight
- The body attempts to add to adipose stores when the body weight falls below the set point and to lose adipose from stores when the body weight rises above the set point.
- Thus, the body defends the set point with weight loss, appetite increases and energy expenditure falls, whereas with overfeeding, appetite falls and energy expenditure may slightly increase
- **A. Genetic contributions:** genetic mechanisms play a major role in determining body weight
 - 1. Biologic origin: The importance of genetics as a determinant of obesity is indicated by the observation that children who are adopted usually show a body weight that correlates with their biologic rather than adoptive parents. Furthermore, identical twins have very similar BMI, whether reared together or apart, and their BMI are more similar than those of nonidentical, dizygotic twins
 - 2. Mutations: Rare, single gene mutations can cause human obesity. For example, mutations in the gene for leptin (causing decreased production) or its receptor (decreased function) result in hyperphagia (increased appetite for and consumption of food) and severe obesity underscoring the importance of the leptin system in regulating human body weight
