

TRAPPIST-1 is an ultracool
dwarf star, in the Aquarius
constellation, approximately
39 light years from earth
(234,000,000,000,000 miles).
It is very dim and small in stellar
terms at just eight per cent
of the mass of our Sun - only
marginally bigger than Jupiter.

All seven planets could have
moons on their surfaces. But
there are three candidates
which have the perfect
conditions for life, lying
within the 'Goldilocks zone',
where it is neither
too hot nor cold.

HOW IT WAS FOUND

The planets were
discovered by
NASA's Spitzer Space
Telescope (pictured above) and ground
telescopes in Chile,
Morocco, Hawaii,
South Africa and the
Liverpool John
 Moores University
Telescope on La
Palma in the Canary
Islands. (pictured right) Estimated
mass and orbits were
based on 'flares' in the
light from their
parent star as they
passed in front of it.

The Liverpool Telescope (LT) is
robotically controlled. The
mounting structure is 38 feet tall
and 20 feet wide. It weighs
around 26 tons. Built around a
60 ft diameter mirror
designed to collect and direct
light towards instruments. The
telescope is protected from the
elements by a shelter that works
like a clam shell. Unlike most
telescopes, the LT is capable of
observing without any human
intervention. After sunset, it
looks at 'weather' conditions and,
if suitable, the telescope will
open up and work its way
through the list of observations
sent to it during the daytime.
