Abstract The purpose of this study was to determine the effect of a 12-week, 3 times per week, 100% maximum heart rate (HR_{max}) interval training program on the heart rate variability (HRV) of sedentary, middle-aged men. The study was a randomized, controlled trial. The subjects were randomly assigned to either an interval training group (n = 10) or a control group (n = 10). The interval training group performed a 12-week, 3 times per week, 100% HR_{max} interval training program. The control group performed no exercise. The HRV was measured at baseline and at the end of the 12-week interval training program. The HRV was significantly higher in the interval training group than in the control group at the end of the 12-week interval training program. The HRV was significantly higher in the interval training group than in the control group at the end of the 12-week interval training program. The HRV was significantly higher in the interval training group than in the control group at the end of the 12-week interval training program.
