**Abstract:** Radio frequency interference (RFI) represents all unwanted signals detected by radio receivers of a telescope. Unfortunately, the presence of RFI is significantly increasing with the technological development of wireless systems around the world. For this reason, RFI measurement campaigns are periodically necessary to map the RFI scenario around a telescope. The Sardinia Radio Telescope (SRT) is an Italian instrument that was designed to operate in a wide frequency band between 300 MHz and 116 GHz. One of the receivers of the telescope is a coaxial cryogenic receiver that covered a portion of the P and L bands (i.e., 305–410 MHz and 1300–1800 MHz) in its original version. Although the receiver was used for years to observe bright sources with sufficient results, its sub-bands can be redesigned considering the most recently evolved RFI scenario. In this paper, the results of a RFI measurement campaign are reported and discussed. On the basis of these results, the new sub-bands of the L-P receiver, together with the design of the new microwave filter selector block of the SRT receiver, are presented. In this way, SRT will cover up to 120 MHz and 460 MHz of  $-3$  dB bandwidth at the P-band (290–410 MHz) and L-band (1320–1780 MHz), respectively. The bands of these filters are selected to reject the main RFI with high levels of amplitude and optimize the estimated antenna temperature and sensitivity of the receiver during the research activities, such as pulsar observations, very long baseline interferometer applications and spectroscopy science.

## 1. Introduction

Radio frequency interference (RFI) consists of unwanted human-made signals detected by a receiver (i.e., radio telescope), such as self-produced spurious signals and harmonics from lower frequency bands, and spread-spectrum signals generated by devices installed in the surrounding area or on space-to-ground transmissions [1]. Currently, the presence of RFI is increasing because of the extensive abuse of wireless technologies around the world [2]. Although the International Telecommunication Union (ITU) assigned several specific frequency bands to the radio astronomy service (RAS) [3], the radio receivers for telescopes are designed and developed with the widest bandwidth as much as possible. In this manner, astronomers can analyze a larger amount of data at several frequencies with respect to the narrow bands dedicated to the RAS. In the receiver design stage, or more generally in a radio telescope development, a trade-off needs to be found in order to have a wide bandwidth with the least number of unwanted signals [4–7].

The unavoidable presence of RFI in the telescope frequency bands increases the estimated antenna temperature, leading to a degradation in the sensitivity of the system. Consequently, the monitoring and mitigation of RFI represents one of the most important aspects to consider for the optimal functioning of a radio telescope. With regards to the monitoring operations, dedicated measurement campaigns are periodically necessary [7–9].
