portional to the logarithm of its a-c input voltage. This logarithmic output is fed to an Esterline-Angus recording milliammeter which records the action of the bolometer, or the hologram. Wavelength posi-

tions on the holograms are determined by interpolation from the characteristic atmospheric bands. A typical hologram is shown in Figure 2.

METHOD FOR DETERMINING THE ATTENUATION

In determining the attenuation by a column of gas it has been standard practice among infrared spectroscopists to compare the energy transmitted through the gas path with that transmitted through an equivalent evacuated column. Such a procedure is, of course, impracticable here, since this would require an evacuated cell of 5,000 yards. An alternative method is used and depends upon the following procedure. It is observed that the radiation at wavelength 2.16μ is independent of the amount of water vapor in the optical path and is, moreover, independent of the haze condition. This may be taken to mean that radiation of this wavelength comes through the atmosphere unattenuated under virtually all conditions. If now the form of the radiation curve of the source were known (it is probably not a black body) an envelope of the initial radiation could be determined using as a scale point the magnitude of the energy transmitted through the atmosphere at wavelength 2.16μ . The actual form of the radiation curve of the source is obtained by making a set of measurements on the
