Osteoporosis in Clinical Practice Piet Geusens, Philip N. Sambrook, Robert

Lindsay, 2012-12-06 When I was a young intern in internal medicine osteoporosis was defined mainly as a fracture occurring in elderly people. However, although plain X-ray examination was recognized as an insensitive way to detect osteoporosis, hypodense bone was already considered as the reflection of the disease. Over the past 20 years considerable progress has been accomplished. In terms of prevalence, incidence, risk factors, and the burden of osteoporosis and low energy fracture, we can appreciate the magnitude of the problem and its impact on quality of life. We are well aware that vertebral fracture, which can be acutely associated with a low clinical expression, leads to significant long-term impairments. The costs for the individual and for the health budget of society are estimated better. We now have a clear definition of the disease, such as low bone mass and architectural defects resulting in increased fragility. For the former part of the definition, the clinician can use accurate and precise tools allowing them to distinguish how their patient's bone mineral content differs from that of a young healthy population in which fracture occurs very rarely. For the second series of fragility determinants, i.e. structure methods, are in rapid progress and will provide information to clinicians on these variables in the near future. Basic and clinical research have allowed major improvements in the understanding of the pathophysiology of the disease. New genes implicated in low and/or high bone mass have been characterized.
