INTRODUCTION

In this review we examine mutations that alter electrical excitability in the nervous system of the fruitfly, *Drosophila melanogaster*, and discuss how these mutations may be used to approach the molecular basis of ionic channel function.

Electrical activity in the nervous system depends on the transient and selective movement of ions across nerve cell membranes. It is best illustrated by the action potential (Hodgkin & Huxley 1952), where the axonal membrane becomes selectively permeable to Na^+ to generate the rising phase. The falling phase is due to loss of Na^+ permeability (inactivation) and increased permeability to K^+ . The key to action potential genesis lies in the nature of ionic permeability changes. Membrane macromolecules that act as ionic channels underlie these changes. In the low permeability condition, the channels are closed. Following an activation event, channels open into a conformation that allows ions to flow through (see Hille 1984, for a recent review).

Many of the most important questions in excitable membrane neurobiology now focus on the molecular nature of ionic channels. One would like to know the molecular features responsible for different ionic
