Applied Scanning Probe Methods II Bharat Bhushan, Harald Fuchs, 2006-06-22 The Nobel Prize of 1986 on Scanning Tunneling Microscopy signaled a new era in imaging The scanning probes emerged as a new instrument for imaging with a precision sufficient to delineate single atoms At first there were two the Scanning Tunneling Microscope or STM and the Atomic Force Microscope or AFM The STM relies on electrons tunneling between tip and sample whereas the AFM depends on the force acting on the tip when it was placed near the sample These were quickly followed by the Magnetic Force Microscope MFM and the Electrostatic Force Microscope EFM The MFM will image a single magnetic bit with features as small as 10nm With the EFM one can monitor the charge of a single electron Prof Paul Hansma at Santa Barbara opened the door even wider when he was able to image biological objects in aqueous environments At this point the sluice gates were opened and a multitude of different instruments appeared There are significant differences between the Scanning Probe Microscopes or SPM and others such as the Scanning Electron Microscope or SEM The probe microscopes do not require preparation of the sample and they operate in ambient atmosphere whereas the SEM must operate in a vacuum environment and the sample must be cross sectioned to expose the

proper surface However the SEM can record 3D image and movies features that are not available with the scanning probes

#### **Atomic and electronic structures of two-dimensional layers on noble metals**

Jalil Shah, 2019-09-04 Two dimensional 2D materials in the form of a single atomic layer with a crystalline structure are of interest for electronic applications Such materials can be formed by a single element e.g. by group IV or group V elements or as a 2D surface alloy As these materials consist of just a single atomic layer they may have unique properties that are not present in the bulk The 111 surfaces of the noble metals Ag and Au are important for the preparation of several 2D materials To investigate the atomic and electronic structures the following experimental techniques were used in this thesis angle resolved photoelectron spectroscopy ARPES scanning tunneling microscopy STM and low energy electron diffraction LEED The 2D structures studied in this thesis include arsenene an As analogue to graphene and As Ag 111 Sn Au 111 and Te Ag 111 surface alloys Arsenene has been thoroughly investigated theoretically for many years and several interesting properties important for next generation electronic and optoelectronic devices have been described in the literature This thesis presents the first experimental evidence of the formation of arsenene A clean Ag 111 surface was exposed to arsenic in an ultra high vacuum chamber at an elevated substrate temperature 250 to 350 C The resulting arsenic layer was studied by LEED STM and ARPES Both LEED and STM data resulted in a lattice constant of the arsenic layer of 3.6 Å which is consistent with the formation of arsenene A comparison between the experimental band structure obtained by ARPES and the theoretical band

structure of arsenene based on density functional theory DFT further verified the formation of arsenene The As Ag 111 surface alloy was prepared by exposing clean Ag 111 to arsenic followed by heating to 400 C This resulted in an Ag<sub>2</sub>As surface alloy which formed by the replacement of every third Ag atom by an As atom in a periodic fashion LEED showed a complex pattern of diffraction spots corresponding to a superposition of three domains of a reconstruction described by a unit cell STM images revealed a surface with a striped atomic structure with ridges characterized by a local 3 × 3 structure ARPES data showed three alloy related bands of which one can be associated with the 3 × 3 structure on the ridges This band shows a split in momentum space around the point along the direction of a 3 × 3 surface Brillouin zone in similarity with a Ge Ag 111 surface alloy Sn Au 111 surface alloys can be prepared with different periodicities An Au<sub>2</sub>Sn phase characterized by a 3 × 3 periodicity and an Au<sub>3</sub>Sn phase with a 2 × 2 periodicity are formed containing 0.33 and 0.25 monolayer of Sn respectively The clean Au 111 surface itself shows a complex reconstruction the so called herringbone structure that can be viewed as a zig zag pattern of stripes described by a 2 × 3 unit cell The replacement of Au atoms by Sn results in change of the periodicity of the herringbone structure to 2 × 3 and 2 × 2 for the Au<sub>2</sub>Sn and Au<sub>3</sub>Sn surface alloys respectively Furthermore the local 1 × 1 periodicity of clean Au 111 is replaced by a 3 × 3 and a 2 × 2 periodicity as is clear from STM images of the respective cases ARPES data are presented for the Au<sub>2</sub>Sn surface alloy which reveal an electronic band structure with similarities to other striped surface alloys In particular the split in momentum space around the point of a 3 × 3 surface Brillouin zone is observed also for Au<sub>2</sub>Sn A Te Ag binary surface alloy can be formed by evaporating 1.3 monolayer of Te onto a clean Ag 111 surface followed by annealing After this preparation LEED showed sharp 3 × 3 diffraction spots that is evidence for a well ordered surface layer ARPES data revealed two distinct electronic bands that followed the 3 × 3 periodicity One of these bands showed a small spin split of the Rashba type The experimental band structure was compared with the theoretical bands of several atomic models of Te induced structures on Ag 111 An excellent fit was obtained for a Te Ag surface alloy with a planar honeycomb structure with one Te and one Ag atom in the unit cell A semiconducting electronic structure of the Te Ag surface alloy was inferred from the ARPES data in agreement with the 0.7 eV band gap predicted by the DFT calculations
