Abstract

Vegetable production is characterised by intensive traffic, particularly during harvest. While tillage is used to remediate harvest-induced soil compaction and prepare seedbeds, both traffic and tillage require significant energy input and negatively impact soil physical and biological properties. Traffic compaction can be permanently eliminated from the crop growth zone by controlling traffic. This requires all implements to have a particular span, or multiple of it, and all wheel tracks to be confined to specific traffic lanes. The production, environmental and economic benefits of Controlled Traffic Farming (CTF) have been demonstrated commercially in the Australian grain and sugar industries. CTF adoption in the vegetable industry is challenged by the difficulty of achieving compatible track gauge and working width across a diverse range of equipment. Wide-span (gantry) tractors (WS) offer a new mechanization pathway for the industry. A WS tractor, spanning 6-12 m, allows multiple conventional implements of different widths to be mounted within the confinement of the span. A prototype Danish WS tractor equipped with an onion harvester shows that mounting harvest equipment on a WS platform is likely to be no more complex than modifying conventional tractor driven or self-propelled harvest machines to allow CTF. Wide, non-trafficked crop beds could provide yield increases of up to 20% in some crops, purely by growing more plants per ha of land, as less area is required for wheel tracks. Improvements in soil structure through the use of CTF can lead to further yield improvements, reduce energy use, and improve water use efficiency, infiltration and drainage. Using a mixed vegetable crop rotation as a modeling case study, it is estimated that CTF based on WS tractors could substantially improve the productivity and environmental sustainability of vegetable production.

Keywords: gantry tractor, controlled traffic farming, soil compaction, bed configuration

INTRODUCTION

Increased competition in the vegetable industry over the past 20 years has necessitated increased production efficiency, which has been achieved through the use of machinery which has become ever more powerful and heavier. This has resulted in increased soil compaction, particularly from harvest operations. Harvest timing to meet optimum quality or market demands often results in vegetables being harvested in wet conditions (Diserens, 2011; Håkansson et al., 1988). Wheel loads of 5-10 t severely increase the risk of deep soil compaction (Diserens, 2011; Moitzl and Boxberger, 2007), which is uneconomic to repair using tillage. Soil compaction has also increased at seedbed depths. In addition to compaction, increased soil degradation has occurred due to the frequency of tillage operations (Cotching et al., 2013).

Despite conclusive evidence from other industries that controlled traffic farming (CTF) systems improve soil conditions, reduce inputs, and improve productivity in general (Tullberg et al., 2007), CTF systems have not been readily adopted in vegetable production. There are a number of possible reasons for this, including influences of topography (McPhee et al., 2013) and a lack of awareness of the productivity penalties of soil damage. However, a key barrier to adoption is the cost and complexity of achieving dimensional integration of machinery, which is a fundamental requirement of controlled traffic (McPhee and Aird, 2013).

CTF systems require all field machinery to have a common track gauge and working
