

**SQL SERVER BACKGROUND**

SQL Server is a client-server RDBMS (Relational Database Management System). All access to data is controlled by the server. It is compatible with MSN, MSN Office products and IBM SCA (Systems Network Architecture). **TRANSACT-SQL** (Structured Query Language) – SQL Server uses the standard known as ANSI SQL-92.

ARCHITECTURE – A layered structure, partially independent of platforms and client applications. The data access applications, including SQL Server itself, are separate from the database interface (OLE DB, ODBC, which translate data formats). Connections are provided and provided by network libraries. Also known as **layers**.

SERVICES – Components that an server can be stopped or started, or configured to start automatically or manually. Services include **MSDQL**, **Server Service** – Processes data operations and provides access control.

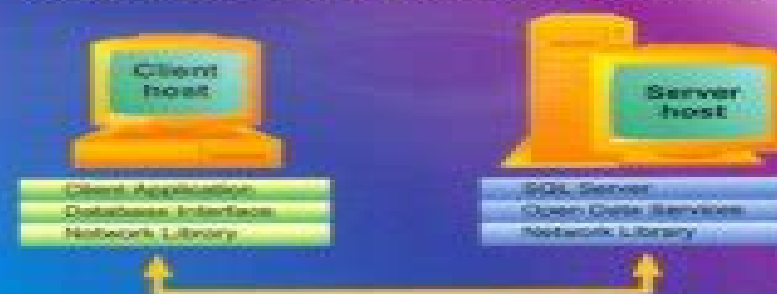

SQL Server Agent Service – Administers jobs and event-driven alerts.

MS Distributed Transaction Coordinator Service – Controls distributed processing, often located on different servers.

MS Search Service – An optional component for full-text searching of databases.

Server Client Software – Used for local or remote management, including setup, networks, Query Analyzer, Enterprise Manager (general administration), Client Configuration, Profile (configures server activity), and Data Transformation Services (import/export).

WINDOWS NT INTEGRATION – The security and operations features. SQL Server does not use a security model, such as authentication and the local Windows NT login authentication controls system. When SQL Server is installed over NT Server, a single login account can be used for both. Each database also has user accounts. Permissions are normally configured using fixed-role user-defined roles.

SQL SERVER ARCHITECTURE**CREATING AND MAINTAINING DATABASES**

A new database is created as a copy of the model database. All databases are described in the master database of SQL Server. **CREATION** – Uses the Database Console wizard, Enterprise Manager, or **CREATE DATABASE**, including options for the name, filename, size, and growth of the database. **ORDER DATABASES** permanently orders the database.

DESIGN – Logical design, which is product-independent, includes several elements.

Tables – Represent a basis of objects representing one or entities joined with attributes (columns). Rows are uniquely identified by primary key values. Columns are defined with characteristics including data type, constraints, and data validation.

Relationships – Inter-table dependencies between the primary key of one table and a foreign key of another table. A unique foreign key creates a 1:1 relation. One-to-many means that the foreign key is not unique. A many-to-many relation is implemented through a junction table in which the two tables each have 1:n relations.

Indexes – A set of rules applied to logical design to enhance query performance. Normalized design often requires multiple or multi-valued columns, repeated data, and unnormalized data in each table, and requires consequences. Normalization generally increases the number of tables and columns, so specific de-normalizations may be used to reduce query overhead.

COMPONENTS – Databases are stored as files on the server: the primary data file (data), secondary data files (data), and log file (log), which holds transaction history.

Pages – Unit of logical design. A page is 8KB of contiguous disk space. A table row occupies a page. It is stored in data type-specific files. Logical design of the database.

Tables – Logical design of the database. One column is 8 pages (64KB). A database has a fixed or variable amount of storage.

Transaction log – Provides a recoverable record of activity and is used to control or roll back transactions. The **log** is a separate process, which logs changes to the data files when inconsistency occurs. If log file disk space is inadequate, transactions will stop.

FILE GROUPS – A database can be configured for automatic growth and for initial and maximum size. Growth is specified in MBs, KBs, or percent. Each file is separately managed with **ALTER FILE**. The data files and the log will typically grow, but at different rates.

Free space – Important to database files. Space free space is efficient. A utility (part of Database Consistency Checker) is used to reduce free space to a specified value. Example: **DBCC SHRINKFILE (name, size, 10)**

Autoshrink – An automatic shrinking database option.

SETTINGS AND INFORMATION – Enterprise Manager or system stored procedures can be used to manage databases.

sp_dboption – Lists and sets database options, including read-only and whether a log is automatically truncated.

sp_helpdb – Returns database information such as size, status, and files.

sp_helpindex – Reports storage used. **INDEXES** – Each database must have at least one index called the database index. (The system catalog in the master database stores metadata about the server itself.) Queries can be optimized on system tables. There are system functions returning specific information. Example: **COL_LENGTH** returns the width of a column. **Information schema views** – Built-in views of metadata concerning data objects. For example, to list all tables in a database:

```
USE master;
SELECT * FROM
```

Information schema tables **DATABASE OBJECTS** – Include databases, tables, columns, views, users, etc. **Object names** – Qualified naming system (prefixed or fully qualified). The fully-qualified name format is:

server.database.schema.object

Ownership is controlled so that the database owner is always the owner. Permissions and ownership are recorded.

DATA TYPES – Data types are needed to create tables. Data types commonly used to specify how information is stored include:

1. **Character** – Fixed-length strings up to 8000 bytes.
2. **Exact numeric** – Numbers is specified by decimal format.
3. **Approximate numeric** – Floating point or double precision numbers.
4. **Object identifier** – A unique identifier (ID type).

User-defined data types – Created using **sp_addtype**, and they are available to all databases. Example:

```
EXEC sp_addtype phoneint,
'char(12)', NOCA
```

This creates a data type for a telephone number.

CREATE TABLES – The table in a database may only have up to 1024 columns. Example syntax:

CREATE TABLE tablename (columnname datatype [NOT NULL], columnname datatype [NOT NULL])

Table constraints – Allow you to perform modifications using **ALTER TABLE**.

ADD CONSTRAINT, ALTER **CONSTRAINTS** – Database and tables can have constraints. For a given database, user-defined SQL scripts in Enterprise Manager. Set the script file to create the same data structure again.

DATA INTEGRITY – The integrity of data includes its accuracy and logical consistency. **Domain integrity** – Specifies valid data in a column.

Entity integrity – Requires that each row be uniquely identifiable by a primary key value.

Referential integrity – Foreign relations. A primary key in a referenced table cannot be changed, nor can the row be deleted, if a foreign key refers to that row. A row cannot be added to a referencing table unless the referenced table contains the specified primary key. For example, you cannot add an order from a non-existent customer, nor delete a customer referred by an order. **User-defined integrity** – Consists of rules created to enforce database constraints.

Enforcement – Depends on declarative integrity design (declarative and procedural integrity) implemented by processing scripts. Integrity is normally declarative, enforced by constraints.

CONSTRAINTS – Constraints prevent inappropriate data from being inserted in columns. However, errors must be handled by the client application.

Constraints on data can be specified with **CREATE TABLE/ALTER TABLE** (one table is both for a list of types). For example, to define a default value for a column:

```
ALTER TABLE name
ADD CONSTRAINT phoneint
```

DEFAULT '000000' FOR phoneint

Checking – Checks declaratively refers a constraint is added to a procedure or database. In system errors, check checking with the **DBCC CHECK** command, and use queries to find and update data that does not conform.

CONSTRAINTS

Constraint Type	Constraint	Description
Domain	DEFAULT	Specifies default value for a column.
	PRIMARY KEY	Value must match primary key of referenced table.
	CHECK	Specifies rule for validating data values.
Entity	PRIMARY KEY	Specifies column for primary key column.
	UNIQUE	Ensures uniqueness of nonprimary key.
Referential	FOREIGN KEY	Defines key expression that must match a primary key of the same or another table.
