**ABSTRACT** Diagonal loading provides a powerful and effective way to improve the robustness of the standard Capon beamformer. Several parameter-free robust adaptive beamformers (RAB) are considered in this paper. We reveal that the performances of them have somewhat degradation when the number of snapshots or that of sensors is large. To solve this problem, we emphatically study the well-known generalized linear combination-based method, the performance of which may degrade severely when the number of sensors increases, and propose a novel parameter-free technique, which is a combination of noise reduction preprocessing technique and truncated minimum mean square error criterion. As most of the parameter-free RAB techniques are very sensitive to the desired signal steering vector mismatch, this paper further proposes to construct a series connection between these RAB techniques and a steering vector estimation (SVE) method, where the SVE is implemented by a convex optimization technique. Simulation results show that the proposed method can achieve a promising performance in comparison with the competing methods.

**INDEX TERMS** Diagonal loading, robust adaptive beamforming, parameter-free, steering vector estimation.

## I. INTRODUCTION

The standard Capon beamformer (SCB) is an optimal spatial filter with remarkable resolution and interference suppression capability [1]. However, it is very sensitive to the imprecise knowledge of the true covariance matrix and the mismatch of the steering vector of signal-of-interest (SOI). In the last half century, many robust adaptive beamformers (RAB) have already been proposed to improve the robustness of SCB. They can be roughly classified into four categories: diagonal loading method [2]–[5], uncertainty set-based method [6]–[11], eigenspace-based method [12]–[14], and interference-plus-noise covariance matrix reconstruction-based method [15]–[18].

Diagonal loading is one of the most widely used RAB method, where a scaled identity matrix is injected into the sample covariance matrix according to some rules [2]. Most of the conventional diagonal loading methods are user parameter dependent. For example, the norm constrained Capon beamforming is a frequently used conventional

diagonal loading method, whose the diagonal loading level is determined by the user parameter upper bound of the square of the weight vector norm [2]. In recent decades, the uncertainty set-based robust adaptive beamformers have been proposed, such as the worst-case performance optimization beamformer [7], the linear programming beamformer [8], and the distributional robust chance-constrained beamformer [9]. They are proved equivalent to the diagonal loading method [6], and their corresponding diagonal loading level can be calculated by the user defined size of the uncertainty set of the array steering vector. Therefore, the conventional diagonal loading method and the uncertainty set-based diagonal loading method have the common problem that their diagonal loading level is uneasy to be determined beforehand.

Several parameter-free RAB techniques have been presented in the literature, including the Hoerl-Kennard-Baldwin (HKB) method [19], the general linear combination-based (GLC) method [20], the spatial matched filter-based (SMF) method [21], and the quadratically
