Designing High-performance and Scalable Clustered Network Attached Storage with Infiniband Ranjit Mario Noronha, 2008

Abstract The Internet age has exponentially increased the volume of digital media that is being shared and distributed Broadband Internet has made technologies such as high quality streaming video on demand possible Large scale supercomputers also consume and create huge quantities of data This media and data must be stored cataloged and retrieved with high performance Researching high performance storage

subsystems to meet the I/O demands of applications in modern scenarios is crucial. Advances in microprocessor technology have given rise to relatively cheap off the shelf hardware that may be put together as personal computers as well as servers. The servers may be connected together by networking technology to create farms or clusters of workstations COW. The evolution of COWs has significantly reduced the cost of ownership of high performance clusters and has allowed users to build fairly large scale machines based on commodity server hardware. As COWs have evolved networking technologies like InfiniBand and 10 Gigabit Ethernet have also evolved. These networking technologies not only give lower end to end latencies but also allow for better messaging throughput between the nodes. This allows us to connect the clusters with high performance interconnects at a relatively lower cost. With the deployment of low cost high performance hardware and networking technology it is increasingly becoming important to design a storage system that can be shared across all the nodes in the cluster. Traditionally the different components of the file system have been strung together using network connections. The protocol generally used over the network is TCP/IP. The TCP/IP protocol stack in general has been shown to have poor performance especially for high performance networks. In this dissertation we research the problem of designing high performance communication subsystems for network attached storage NAS systems. Specifically we delve into the issues and potential solutions with designing communication protocols for high end single server and clustered server NAS systems. Orthogonally we also investigate how a caching architecture may potentially enhance the performance of a NAS system. Finally we look at the potential performance implications of using some of these designs in two scenarios over a long haul network and when used as a basis for checkpointing parallel applications.

**System Architecture Design for High Performance Solid-state Data Storage Devices** Xubin Chen, 2020      Beyond Storage Interfaces Jun He, 2019

Efficient interactions between the software and storage devices are essential for achieving high performance in data processing systems. However efficient interacting is challenging because such interactions are beyond the storage interfaces complying with the specifications of the interfaces which we call written contracts. This does not guarantee high performance. To achieve high performance clients of storage devices must follow an additional set of implicit rules which we call unwritten performance contracts. The specific unwritten performance contract of a device depends on its internal architecture. Violating the contract lowers the performance of the data processing system. As a result we must find violations of the unwritten contract and exploit the contract to achieve high performance. We start by finding violations of the unwritten contracts for HDDs and SSDs respectively. First we study the methodologies for finding violations of the HDD unwritten contract by using statistical methods e.g. Latin hypercube sampling and Sensitivity Analysis. Our study finds and fixes four design issues in a popular file system Linux ext4. Second we find violations of the SSD unwritten contract by full stack analysis of modern applications file systems and SSD FTLs. We begin by formalizing the rules of the SSD unwritten contract we then conduct analysis to uncover application and file system designs that violate the contract. As a result we make numerous interesting

observations that could shed light upon the future storage system designing Finally we exploit the unwritten contract of SSDs to build a cost effective and high performance data processing system To this end we propose Tiny Memory Processing Systems TMPS which exploit fast and cheap SSDs to reduce expensive memory To study the TMPS approach we build a complete search engine that employs careful designs in data layout early pruning prefetching and space traffic tradeoffs When compared with a state of the art search engine in a tiny memory configuration our search engine reduces I O amplification by up to 3.2 times query latency by up to 16 times and increases the query throughput by up to 2.9 times
