This is due to recent technological advances, primarily computerization. The methods employed in CNS diagnostics are collectively referred to as neuroimaging and include procedures for investigating both cerebral morphology and cerebral function such as computed tomography, CT, magnetic resonance imaging, MRI, positron emission tomography, PET, and single photon emission computed tomography, SPECT. Topographic mapping of electroencephalograms, EEG, and evoked potentials represents one of the functional procedures and permits topographic imaging of EEG, evoked potentials, and magnetic fields. The latter application includes not only magnetic fields evoked by stimuli relating to different sensory modalities but also endogenous and motor fields resulting from spontaneous brain magnetic activity as recorded by magnetoencephalograms, MEG. The magnetic complement of the EEG. The advantage of recording electric and magnetic fields over other neuroimaging procedures is that these techniques are completely noninvasive and have extremely short analysis times in the millisecond range. The aim of this book is to clarify the current state of this emerging technology, to assess its potential for substantive contributions to brain research, to delineate areas for further research, and overall to envisage clinical applications in disciplines such as psychiatry, neurology, and neuropsychology. *Computer Vision, Virtual Reality and Robotics in Medicine* Nicholas Ayache, 2006-04-10 This book contains the written contributions to the program of the First International Conference on Computer Vision, Virtual Reality
