## Can you treat type IIA supracondylar humerus fractures conservatively?

There is good general literature and surgical consensus that type I supracondylar humerus fractures can be treated with short-term cast immobilization, while type II supracondylar humerus fractures should be treated with closed reduction and percutaneous pin fixation in order to avoid long-term deformity and disability. Given what is perceived as a relative low morbidity of percutaneous pinning and a desire to avoid malunion or late displacement, type II supracondylar humerus fractures have also often been treated with percutaneous pin fixation and casting; indeed, this is the current clinical practice guideline from the American Academy of Orthopaedic surgeons. However, there are centres where these injuries are successfully treated non-operatively. In this paper, which piqued our interest here at BJ360, researchers from **San Diego (California, USA)** sought to add to the literature.<sup>1</sup> Their paper compared nonoperative and operative treatment of patients with type IIA fractures that have no signs of coronal malalignment and or malrotation. Over a two-year period, 105 patients between the ages of two and 12 years presented with a type IIA supracondylar fracture and were enrolled to the study

prospectively. Patients with prior elbow trauma, metabolic, or neuromuscular diseases were excluded from recruitment. The reported cohort were managed by ten surgeons, with five preferring surgical operative management and five preferring an initial attempt at nonoperative management. Nonoperatively-treated patients had a long arm cast applied with close follow-up of radiographs; a standard protocol was used, which included three to four weeks of casting and bilateral elbow radiographical follow-up at six months postinjury with a follow-up via telephone at six, 12, and 24 months. Overall, the authors included 99 patients, with 45 nonoperative cases and 54 cases, who were managed operatively. Up to and including the first clinic follow-up, 9% of nonoperative patients were converted to surgery. There were no differences between the cohorts in terms of demographic

details, but patients who underwent surgery had a small but statistically significant greater posterior mean angulation deformity of 6° more than their nonoperative counterparts. At the final follow-up, which was performed at a mean of six months postinjury, the nonoperative group had slightly more extension on radiographs; however, this was within a clinically insignificant range of approximately 3°. There were no other clinical radiographical differences between the groups, with complications occurring at similar frequencies. Overall, 4.4% compared with 5.6% of the operative group suffered a refracture. Avascular necrosis rates were similar at 2.2% in the nonoperative group and 1.9% in the operative group. Unfortunately this was not a randomized trial and treatment protocols were not uniformly applied. However, there is a very clear take home message here: comparable results can potentially be achieved in the treatment of type IIA supracondylar fractures. A randomized trial would settle the matter.
