The role of hypoxia for the development of diabetic nephropathy Stephanie Franzén, 2016-03-09

Diabetic nephropathy is one of the most common causes of end stage renal disease and develops in approximately one third of all diabetes patients Disease progression is characterized by deteriorating glomerular filtration rate and escalating urinary albumin protein excretion both are used as clinical markers for disease progression Recently it has been proposed that intrarenal hypoxia is a unifying mechanism for chronic kidney disease including diabetic nephropathy Several mechanistic pathways have been linked to the development of intrarenal hypoxia and diabetic nephropathy including increased angiotensin II signaling oxidative stress and hyperglycemia per se Furthermore pathological endothelin signaling has recently emerged as a possible contributing factor for chronic kidney disease and diabetic nephropathy The overall aims of this thesis were therefore to determine the temporal relationship between development of intrarenal hypoxia and kidney disease as well as elucidate the potential link between endothelin signaling intrarenal hypoxia and kidney disease in experimental insulinopenic diabetes It is well established that different mouse strains have different susceptibility for kidney and cardiovascular disease The first step was therefore to compare four commonly used mouse strains with regards to development of kidney disease after onset of insulinopenic diabetes From the results of this study we concluded that the NMRI mouse strain has a disease progression closest to the human disease and this strain was chosen in the subsequent studies in mice The next step was to adapt and optimize a suitable method for repetitive measurements of intrarenal oxygen tension during the course of disease development Electron paramagnetic resonance EPR oximetry had previously been used in tumor biology and was now adapted and optimized for measurements of kidney oxygenation in our diabetic mouse model EPR oximetry in normoglycemic control mice recorded cortical oxygen tension values similar to previous reports using

invasive techniques Surprisingly intrarenal hypoxia developed already within the first 72h after induction of hyperglycemia and persisted throughout the two week study period Importantly this was well before albuminuria developed The final part of this thesis was to investigate the role of endothelin signaling for the intrarenal hypoxia in a diabetic rat model Endothelin 1 signals via two distinctly different receptor mediated pathways In normal physiology endothelin 1 binding to endothelin receptor type A ETA induces vasoconstriction which can be blocked by the specific ETA antagonist BQ123 whereas endothelin 1 binding to endothelin receptor type B ETB induces nitric oxide dependent vasodilation ETB receptors can be selectively activated by Sarafotoxin 6c The results from blocking ETA and activating ETB receptors demonstrated that endothelin 1 signaling via ETA receptors contributes to intrarenal hypoxia in the rat diabetic kidney and that ETB stimulation significantly reduces the diabetes induced intrarenal hypoxia The beneficial effects on kidney oxygen availability in diabetes by ETA blockade or ETB stimulation were mainly linked to hemodynamic improvements rather than direct effects on kidney oxygen consumption or oxidative stress status In conclusion by applying EPR oximetry in a mouse model of insulinopenic diabetes mimicking the human disease we demonstrated intrarenal hypoxia already within the first couple of days after the onset of hyperglycemia which is well before detectable signs of kidney disease development Furthermore blockade of ETA or activation of ETB receptors significantly reduced intrarenal hypoxia in the diabetic kidney These results demonstrate involvement of ETA receptor signaling in diabetes induced intrarenal hypoxia and ETA blockade or ETB activation might provide new therapeutical targets to reduce kidney hypoxia and disease progression in diabetes
