PHOTOGRAPHIC SENSITIVITY: A COLLOID
CHEMICAL PROBLEM.[†]

By S. E. Sheppard.

IN A paper presented at the Colloid Symposium at Madison in 1923, the author discussed one important factor affecting photographic sensitivity. This is grain-size, or dispersity of the silver halide, and the distribution of grain-sizes in one and the same emulsion. It was shown then that in one and the same emulsion sensitivity increases statistically with the size of grain in the sense that the chance of a grain being made developable by a given exposure increases with the size (projective area). Other factors intervene, however, as between one emulsion and another, so that average grain-size is not the sole factor conditioning sensitivity.

It was found several years ago by Lüppo-Cramer that the sensitivity of plates could be greatly diminished by treatment before exposure with chromic acid, followed by thorough washing to remove the chromic acid. This desensitizing reaction has been quantitatively investigated in recent years both in England and in this country, and the results of the work are discussed in this paper. It is concluded that high photographic sensitivity is connected with something other than silver halide which is formed in the grains. Experiments by the author are described which show that emulsions made in the same manner, and having the same grain-size properties, can have quite different photographic sensitivities and properties according to the gelatin used. Hence, it is concluded that the substance in question is specifically afforded by the gelatin.

The content of this monograph stems from the writer's early involvement with the design of a series of television camera tubes the orthicon the image orthicon and the vidicon These tubes and their variations have at different times been the eyes of the television system almost from its inception in 1939 It was natural during the course of this work to have a parallel interest in the human visual system as well as in the silver halide photographic process The problem facing the television system was the same as that facing the human visual and the photographic systems namely to abstract the maximum amount of information out of a limited quantity of light The human eye and photographic film both represented advanced states of development and both surpassed in their performance the early efforts on television camera tubes It was particularly true and plain to see that each improvement and refinement of the television camera only served to accentuate the remarkable design of the human eye A succession of radical advances in camera tube sensitivity found the eye still operating at levels of illumination too low for the television camera tube It is only recently that the television camera tube has finally matched and even somewhat exceeded the performance of the human eye at low light levels It was also clear throughout the work on television camera tubes that the final goal of any visual system biological chemical or electronic was the ability to detect or count individual photons Scientific and Technical Books and Serials in Print ,1984 *Books in Print Supplement* ,1984
