

of them, controlled by RCG. The notch filter is a bridged-T network, which can be made to discriminate very sharply against a narrow frequency band, without affecting response to frequencies removed only a few cycles from the limits of the notch. The depth of the notch, that is, the amount by which the level of the reverberation presented to the ear is attenuated with respect to the level of the received reverberation, can be controlled by an RCG circuit, in such a manner that the relations shown in the lower diagram are preserved at all times when appreciable amounts of reverberation are received. It would probably be desirable to leave the reverberation distinctly audible, to provide a pitch reference for doppler judgment.

Such a procedure would, of course, have no beneficial effect on the detectability of undopplered echoes. In fact, it would probably raise the recognition differentials for such echoes by introducing distortion and by dropping the stimulation level at the reverberation frequency. Its advantage for dopplered echoes, which may become increasingly important for the high-speed submarine recently developed, is obvious from the lower diagram in Figure 9.

In order to eliminate the effects of own-doppler, which would generally cause the frequency of the received reverberation to fall outside the limits of the notch filter, it would be necessary to rely on ODN or some other method of stabilizing the pitch of the received reverberation. ODN is an electronic device which samples the frequency of the received reverberation for a short interval immediately after each transmission. If the frequency of this short sample of reverberation is modified by own-doppler, the ODN unit alters the frequency of the heterodyne oscillator in such a manner that the output frequency of the reverberation at greater ranges is held to a constant value for a wide range of ship speeds and hydrophone orientations.

10.2.6

Effects of Headphone and Loudspeaker Presentation

These tests with headphones and loudspeaker presentation were undertaken in order to evaluate the significance of field reports re-

ceived by the British which stated⁴ that "weak echoes are sometimes detected on the loudspeaker when they are inaudible in the [headphones]." Similarly, it had been reported "that, with echoes of fair strength, doppler is readily noticeable on the loudspeaker, while at the same time no doppler is reported from the operator using the [headphones]."

Sixteen observers were tested on their ability to hear 70-millisecond pulses with various amounts of doppler in the presence of reverberation. The test procedure was the same as that described in the previous sections. Each observer was required to identify the level of the prismaudible pulse, to state whether its frequency was the same as that of the reverberation, and, if not, to specify whether its frequency was higher or lower than that of background. In the present section, the discussion is concerned solely with the effect of loudspeaker and headphone presentation upon ability to detect dopplered and undopplered pulses.

Range and bearing were fixed. Each listener made fourteen observations, corresponding to seven doppler conditions (0, ± 20 , ± 40 , and ± 60 cycles), repeated with loudspeaker and headphones. The amount of doppler was varied at random among the seven conditions stated, and the effect of variation in reverberation level with time was minimized by alternating frequently between loudspeaker and headphone presentation. Since the tests extended over a period of several days, the difference in performance obtained by the two presentation

FIGURE 10. Effect of loudspeaker and headphone presentation on the detectability of pulses.

methods is much more significant than is the absolute level of performance. However, the latter, shown for both presentation methods in Figure 10, is in fair agreement with that shown in Figure 5.

Pawel Strumillo,2011-04-11 Sound source localization is an important research field that has attracted researchers efforts from many technical and biomedical sciences Sound source localization SSL is defined as the determination of the direction from a receiver but also includes the distance from it Because of the wave nature of sound propagation phenomena such as refraction diffraction diffusion reflection reverberation and interference occur The wide spectrum of sound frequencies that range from infrasounds through acoustic sounds to ultrasounds also introduces difficulties as different spectrum components have different penetration properties through the medium Consequently SSL is a complex computation problem and development of robust sound localization techniques calls for different approaches including multisensor schemes null steering beamforming and time difference arrival techniques The book offers a rich source of valuable material on advances on SSL techniques and their applications that should appeal to researches representing diverse engineering and scientific disciplines **Ocean Observation based on Underwater Acoustic Technology, volume II** Xuebo Zhang,Haixin

Sun,Arata Kaneko,Suleman Mazhar,2024-12-02 Since the sound wave is the only information carrier that can propagate long distances in the ocean underwater acoustic technology based on sound waves undoubtedly plays an important role in ocean observation The development of underwater acoustic technology requires the support of various underwater acoustic sensors and signal processing techniques The function of an underwater acoustic sensor is to conduct the conversion between an underwater acoustic signal and an electric signal Their performance directly determines the quality of underwater acoustic equipment However the harsh environment such as high pressure high temperature and highly corrosive fluids as well as different requirements such as low frequency broad bandwidth high power and deep water often affect the physical properties of materials and structural performance of transducers which deteriorates the transducer performance Due to the lack of comprehensive research on key techniques including material physical properties and interfacial bond properties the reliability of structural components is often seriously affected by environmental conditions which may lead to major performance degradation or even failure with the device performance Therefore it is challenging for the transducer design to balance the acoustic performance and the device s stability *Microfilm Index* United States.
