Abstract: Lymphoma is one of the hematologic malignancies that occur at a higher rate in human immunodeficiency virus-infected individuals. It is one of the most frequent neoplastic causes of death in these individuals. Non-Hodgkin's lymphoma and Hodgkin's lymphomas are acquired immunodeficiency syndrome defining lymphoma and non-acquired immunodeficiency syndrome defining lymphoma, respectively. Non-Hodgkin's lymphoma is the most common type of lymphoma in human immunodeficiency virus-positive people. The lymphoma that develops in patients infected with the human immunodeficiency virus/acquired immunodeficiency syndrome is heterogeneous in terms of morphology, pathogenesis pathways, and cellular derivation. A narrative review was conducted on the basis of relevant literature on the current topic to summarize the current epidemiology, pathogenesis, laboratory diagnosis, and treatment of lymphoma in human immunodeficiency virus-infected patients. The finding showed that although the incidence of non-Hodgkin's lymphoma has decreased after the advent of highly active antiretroviral therapy, it has remained higher in human immunodeficiency virus-infected people than in the general population. On the other hand, the incidence of Hodgkin's lymphoma has increased after the introduction of highly active antiretroviral therapy. Therefore, it is recommended that people living with human immunodeficiency virus/ acquired immunodeficiency syndrome be screened for the development of lymphoma to increase their survival time and quality of life, and further research is required regarding the pathogenesis, treatment, and laboratory diagnosis of human immunodeficiency virus/ acquired immunodeficiency syndrome-associated lymphoma.

Introduction

Background Information

Globally, the Human Immunodeficiency Virus (HIV) it remains a critical health problem; as of 2020, 37.7 million and 1.5 million people were living with HIV (PLWHIV) and newly infected with HIV worldwide, respectively. In addition, nearly 680,000 people died from diseases associated with Acquired Immunodeficiency Syndrome (AIDS).¹ HIV-infected people are more likely to develop the various disease, including cancer. Severe immunosuppression occurred at advanced HIV infection is a risk factor for the occurrence of a variety of malignancies.²

Malignancies have become the leading cause of morbidity and mortality in HIV-positive people as their life expectancy has improved in the highly active antiretroviral therapy (HAART) era.³ As a result, malignancies develop in 25% to 40% of people living with HIV/AIDS.⁴ More than 28% of HIV-related deaths are attributed to malignant tumors, and more than 40% of HIV-infected people are eventually diagnosed with AIDS-associated lymphomas.⁵

HIV/AIDS-associated lymphomas are hematological neoplasms that develop from T and B lymphocytes, immune system cells, at various stages of differentiation.⁶ Nearly 90% of lymphoma originates from B cells, and some distinct subtypes of lymphomas are more common than the other types. Some of these can occur among both HIV-infected and non-infected people, whereas others appear to be more common in HIV-infected people.³ HIV/AIDS-associated lymphomas are malignancies that have fast-spreading and invasive characteristics. If left untreated, it can lead to death within weeks or months after being diagnosed.⁴ In the early times, HIV/AIDS-associated lymphomas had been described by morphology and primary location of lymphomas, such as systemic, primary central nervous system, and
