II C. Esling, 2005 Natural as well as man made materials are often assumed to behave uniformly exhibiting equal strength in all directions because most of them have a polycrystalline structure The anisotropy of the individual crystals however is smoothed out only in the presence of a large number of grains having a random distribution of orientations In reality there usually remains an anisotropy due to the existence of preferred orientations Its magnitude depends upon the statistical distribution of grain orientations the crystallographic texture or more simply the texture This governs the extremes of the physical property of interest which a single crystal of the material under consideration can exhibit in directional tests Local variations in texture as well as the arrangements and types of grain phase boundaries may give rise to inhomogeneous material properties The texture also carries with it information on the history of a material s processing use and misuse A knowledge of the texture is a prerequisite for all quantitative techniques of materials characterization and is based upon the interpretation of diffraction peak intensities It is also necessary to model the relationships between microstructural features and physical or mechanical properties Therefore the texture is of great value for quality control in a wide range of industrial applications and in basic materials research
