Free energy of a reaction

The **free energy change** (ΔG) of a reaction determines its spontaneity. A reaction is spontaneous if ΔG is negative (if the free energy of products is less than that of reactants).

For a reaction $A + B \leftrightarrow C + D$

$$\Delta G = \Delta G^{\circ'} + RT \ln \left(\frac{[C][D]}{[A][B]} \right)$$

Chapeville, A. L. Haenni, 2012-12-06 Studies of chemical recognition in biology were initiated about half a century ago with the first kinetic data obtained on enzyme catalysis and inhibition They led to a rather static representation of the recognition process illustrated by the lock and key model that still continues to influence our overall image of recognition and its specificity In several cases crystallographic studies of enzyme substrate complexes have supported this model Indeed in a crystallized ligand enzyme complex a close fitting is observed between the active center of the enzyme and the functional groups of the ligand However this does not necessarily result from a direct recognition process between rigid structures but may result from a progressive adaptation during which the initial structures of the enzyme and the ligand are modified induced fit mechanism Recently a great deal of work has been devoted to the study of recognition in more complex systems such as the replication or the translation machines clearly the extraordinary precision of such systems cannot be explained solely in terms of physical matching between enzymes and their substrates This has led to a noticeable change of perspective in these areas As a result of the new kinetic viewpoint one rather focuses on the time course of the processes on the kinetic balance between steps of the reaction on the energy accuracy relationships and on the strategies which permit the achievement of high precision using relatively error prone components in an appropriate dynamic interplay Biochemistry David E. Metzler, Carol M.
