In this study, the complete residual stress tensor has been determined by X-ray diffraction, using the $\sin^2\psi$ method, in 1000 and 2500 Å tungsten thin films deposited by ion beam sputtering on a silicon monocrystal. In the first case, we found very high tension stresses (about 1.5 GPa) for the as-prepared state and important compressive stresses (about -1.3 GPa) after an implantation with a dose of 10^{16} Xe^{2+} ions/ cm^2 at 320 keV. In the second case, the film was almost detached from its substrate and the stresses were compressive (about -0.9 GPa). In all cases, the free-stress lattice parameter was different from the bulk one, indicating significant differences between the microstructure of these thin tungsten films and the one of the bulk. The size of the coherent domains of diffraction was also determined and was found to largely vary from one case to the other.

1. Introduction

The development of thin films is constantly increasing because of their electrical, optical, mechanical, tribological properties, and their corrosion resistance. Residual stresses influence the majority of these properties and their knowledge is therefore very important. The subject has been studied by various methods such as curvature measurements [1–3], symmetrical X-ray diffraction [4], Raman spectroscopy [5], photoelectric

effect [6], and non-symmetrical X-ray diffraction using the $\sin^2\psi$ method [7]. Contrarily to the other methods, the last one is the only one which allows the whole stress tensor to be determined without any hypothesis (except the necessary $\sigma_{33} = 0$, where 3 is the axis normal to the film surface (see fig. 1). This method is used in this study. We will recall here its main principles and for a complete presentation, see for example refs. [7–10].

2. Principles of the $\sin^2\psi$ method

The method is based on the derivative of the Bragg law

$$2d \sin \theta = \lambda, \quad (1)$$

which gives

$$\Delta d/d = \epsilon_{\phi\phi} = -\cos \theta \Delta \theta, \quad (2)$$

where ϕ and ψ are the Euler angles (see fig. 1), d is the interreticular distance of the diffracting family $\{hkl\}$, $\Delta \theta = \theta - \theta_0$, θ being the diffraction angle of the $\{hkl\}$ planes in the stressed film
