Information Technologies and Mathematical Modelling. Queueing Theory and Related Fields Alexander Dudin, Perspectives in Operations Research Frank B. Alt, Michael C. Fu, Bruce L. Golden, 2006-12-26 A Symposium was held on February 25 2006 in honor of the 80th birthday of Saul I Gass and his major contributions to the field of operations research over 50 years This volume includes articles from each of the Symposium speakers plus 16 other articles from friends colleagues and former students Each contributor offers a forward looking perspective on the future development of the field Handbook of Transportation Science Randolph Hall, 2012-12-06 Over the past thirty five years a tremendous body of both theoretical and empirical research has been established on the science of transportation The Handbook of Transportation Science has collected and synthesized this research into a systematic treatment of this field covering its fundamental concepts methods and principles The purpose of this handbook is to define transportation as a scientific discipline that transcends transportation technology and methods Whether by car truck airplane or by a mode of transportation that has not yet been conceived transportation obeys fundamental properties The science of transportation defines these properties and demonstrates how our knowledge of one mode of transportation can be used to explain the behavior of another Transportation scientists are motivated by the desire to explain spatial interactions that result in

movement of people or objects from place to place Its methodologies draw from physics operations research probability and control theory It is fundamentally a quantitative discipline relying on mathematical models and optimization algorithms to explain the phenomena of transportation The fourteen chapters in the handbook are written by the leading researchers in transportation science in an effort to define and categorize for the first time the scientific nature and state of the art of the field As such it is directed to the broader research community transportation practitioners and future transportation Data-Driven Insights for Supply Chain Optimization: Frameworks and Solutions using AI Anil K Anusuru, 2025-02-08 Our supply chain SC model is based on a two tier queueing inventory system This facility delivers packages of Q 0 fixed size items from its inventory stored in a distribution centre DC to a retail shopping mall RSM This RSM processes customer requirements through an M M1 M2 1 K rule service facility Requests to the RSM node follow the Poisson process with the parameter The inventory guideline applied at node RSM is of type 0 Q and the order of most items Q 0 is placed on the DC when inventory decreases from Q to level 0 with a threshold guideline called f policy Thus at the end of the delay the DC output of the quantity ordered by RSM is exponentially distributed with the parameter 0 For each request to the RSM node an article is only available after the exponential service time with the parameter 0 The waiting room at the commercial node has unlimited capacity This SC management SCM is called a queue inventory system with a f1 policy The common stochastic process Z t N t I t to link the number of customers demands available at time t by N t and the on hand inventory level by I t is formulated Because of the properties of the exponential distributions and of the f1 policy this pair sequence Z t forms a Markov decision process MDP that changes its states with the passage of times t The Z systems stationary properties are checked at service completion. We also use the linear function of total expected cost to determine the optimal order quantity and optimal order patterns Using the same methodology the analysis is extended by assuming that the two processes are independent under a new policy f2 Numerical illustrations are also provided to support the results obtained from the proposed MDP approach Capacity Oriented Analysis and Design of Production Systems M.B.M. de Koster, 2012-12-06 In production systems there are often capacity oriented performance objectives like a desired total throughput a desired average throughput time and average work in process Such performance objectives are expressed in units of products rather than in specific product types This book presents a way of modeling and analyzing production systems so that such capacity oriented performance criteria can be measured in a simple way The model consists of three basic elements 1 The product types in the system are aggregated 2 The product flow is modeled as being continuous 3 The machines in the model have a finite number of states Each state has a phase type sojourn distribution and an associated production speed Transitions between the states are determined by an irreducible Markov transition matrix In the book both the mathematical properties and the practical applicabilities of the model are investigated. The model is extensively analyzed for various layouts like flow lines assembly disassembly systems and networks where parallel machines share common

buffers Furthermore various ways of controlling the product flow in the model are investigated such as Base Stock Control Workload Control control by finite buffers and control by the Reorder Point System An approximation technique is developed for a quick estimation of performance measures like throughput and average work in process for networks with layouts and control techniques like those above mentioned *Queueing Theory, a Problem Solving Approach* Leonard Gorney,1981
