Cardiac Arrhythmias: New Therapeutic Drugs and Devices J. Morganroth, E. Neil Moore, 2012-12-06 In summary there are many animal models that are useful in selecting new antiarrhythmic drugs The selection of which model is most ideal depends upon precisely what question is being asked The large number of experimental models used to evaluate antiarrhythmic compounds points out the inability of any one model to define the probability of antiarrhythmic efficacy in man It has therefore become standard practice to utilize a battery of animal models for the evaluation of new antiarrhythmic agents Each model has its own advantages and disadvantages and it is necessary to understand each model fully in order to evaluate experimental findings and apply them to clinical settings We believe that the availability of the chronic myocardial infarction ventricular tachyarrhythmia model provides 1 an excellent opportunity to more precisely understand arrhythmia mechanisms 2 to develop new techniques such as signal averaging for evaluating late low level potentials identifying hearts at high risk of sudden death 3 to identify new antifibrillatory drugs versus drugs that are effective primarily against PVCs and ventricular tachycardia 4 to identify new surgical techniques to eliminate VT VF and 5 to evaluate new pacing modalities including implantable cardioverters Although all animal models are wrong many are very useful in furthering our knowledge directed at decreasing the distressingly high mortality from heart disease
