River and Canal Engineering E S Bellasis,1913 **Black River Canal** Edward P. Fynmore,Harney J. Corwin,2005-07
Black River Canal documents in images how a manmade river transformed a region This upper New York State canal was an improbable engineering success In 1825 DeWitt Clinton proposed construction of a canal that would link the Erie Canal at Rome with the Black River at Lyons Falls The idea was well received but the obstacles were great The canal would have to run uphill In the end the 35 mile overland canal required a record 109 locks to negotiate a rise and fall of 1 079 feet Construction was authorized in 1836 and against all odds the Black River Canal was fully operational in 1855 The canal brought a measure of prosperity to an isolated region of the state and promoted development of a wood products industry that continues to this day Statement of the Claim of the Milwaukee and Rock River Canal Company, on the Canal Fund

River and Canal Engineering; the Characteristics of Open Flowing Streams, and the Principles and Methods to by Followed in Dealing with Them Edward Skelton Bellasis,2013-09 This historic book may have numerous typos and missing text Purchasers can usually download a free scanned copy of the original book without typos from the publisher Not indexed Not illustrated 1913 edition Excerpt the stream is ill defined and the flow fitful the rainfall figures may afford the only or at least far the best means of estimating the discharge The rainfall to be considered in all these cases is the maximum likely to fall in a short period of time The catchment areas dealt with are small say 5 square miles or less It must be assumed that the fall of rain extends to all parts of the catchment area and that its duration is sufficient for the water from all parts of it to reach the site of the work The different valleys or divisions of the catchment area should be considered separately and regard must be had not only to the area of each division but to its length and declivity measured along the course of the stream which drains it On these two factors depend the time taken by the rain water to reach the site of the work The rate at which the rain water flows over the ground into rills or small subsidiary

streams may be taken to be mile per hour in flat land and 1 mile per hour on steep hill sides The velocity of the current in the rills and larger streams is generally 2 to 4 miles per hour It can when necessary be calculated roughly from the size and slope of the stream To be on the safe side the highest probable figure can be taken The time taken by the water to flow from the furthest points of the catchment area to the site of the work having been arrived at as above the next thing is to estimate the probable maximum intensity of the rainfall during that time over the whole catchment area The only figures immediately available will be the mean annual rainfall or perhaps the maximum fall in twenty four hours but it has been shown chap II Art 5 how the probable maximum fall over a shorter period
