Immo Appenzeller, 2009-06-17 The high redshift galaxies became a distinct research field during the final decade of the 20th century At that time the Lyman break technique made it possible to identify significant samples of such objects and the new generation of 8 to 10 m telescopes resulted in the first good spectroscopic data Today the high redshift galaxies have developed into one of the important topics of astrophysics accounting for about 5-10% of the publications in the major scientific journals devoted to astronomy Because high redshift galaxies is a rapidly developing field and since new results are published constantly writing a book on this topic is challenging On the other hand in view of the large amount of individual results now in the literature and in view of the still growing interest in this topic it appears

worthwhile to summarize and evaluate the available data and to provide an introduction for those who wish to enter this field or who for various reasons might be interested in its results. The end of the first decade of the 21st century appears to be a good point in time to attempt such a summary. The current generation of ground based 8 to 10 m optical telescopes, the Hubble Space Telescope and the most important large radio telescopes have by now been in operation since about one or two decades. Although these instruments will continue to produce important scientific results for some time to come, many of the initial programs exploiting their unique new possibilities have been completed.
