

Pathology – pulmonary tumors

Carcinoma

- Most lung cancers are associated with cigarette smoke
- The increased risk is 60 times greater in habitual heavy smokers than in non-smokers
- The carcinogenic effects of tobacco extend to second hand smokers

Classification

- Broadly classified into small cell and non-small cell types, with the latter group including adenocarcinoma and squamous cell carcinoma
- Lung carcinomas may arise in the peripheral lung (more often adenocarcinomas) or in the central/ hilar region (more often squamous cells carcinomas), sometimes in association with recognizable precursor lesions

Adenocarcinoma

- More common in women
- is associated with tobacco smoking, but less so than other subtypes
- Invasive malignant epithelial tumor with glandular differentiation
 - Often with mucin production by the tumor cells
- Adenocarcinomas grow in various patterns
 - Acinar, Lepidic (tumor cells crawl along normal appearing alveolar septa), Papillary or micropapillary, Solid
- Lesions are more peripherally located
 - The majority express thyroid transcription factor-1 (TTF-1 -), a protein first identified in the thyroid that is required for normal lung development

Atypical adenomatous hyperplasia with cuboidal epithelium and mild interstitial fibrosis.

Gland-forming adenocarcinoma; inset shows thyroid transcription factor 1 (TTF-1) positivity, which is seen in a majority of pulmonary adenocarcinomas.

Lepidic adenocarcinoma, consists of atypical type II pneumocytes or Clara cells growing along the surface of alveolar septa.

Adenocarcinoma of lung, acinar type. Small acini are infiltrating in linear clusters through desmoplastic stroma. Note the anthracotic pigment on the lower left

Solid adenocarcinoma, the major tumor component consists of solid sheets and lacks other recognizable patterns of adenocarcinoma
