This study reports quantitative measurements of the accuracy of two popular voxel-based registration algorithms—Woodard automated image registration algorithm and mutual information correlation—and compares these with conventional surface matching (SM) registration. **Methods:** The registration algorithms were compared (15 different matches each) for (a) three-dimensional brain phantom images, (b) an ideal SPECT image from a patient with partial epilepsy matched to itself after modification to simulate changes in the cerebral blood flow pattern and (c) icteroheterotaxial SPECT images from 15 patients with partial epilepsy. Blinded visual ranking and localization of the subtraction images derived from the patient images were also performed. **Results:** Both voxel-based registration methods were more accurate than SM registration ($P < 0.0005$). Automated image registration algorithm was more accurate than mutual information correlation for the computer-simulated icteroheterotaxial images and the patient icteroheterotaxial studies ($P < 0.05$). The subtraction SPECTs from SM were poorer in visual ranking more often than the voxel-based methods ($P < 0.05$). **Conclusions:** Voxel intensity-based registration algorithms provide significant improvement in icteroheterotaxial SPECT registration accuracy and result in a clinically detectable improvement in the subtraction SPECT images.

Several computer-aided methods for producing subtraction ictal SPECT images coregistered to MRI (SISCOM) have recently been described as tools for improving the localization of the epileptogenic zone in focal epilepsy (1–4). These methods have been shown to significantly improve sensitivity and specificity compared with conventional visual analysis of icteroheterotaxial SPECT images (3,5,6). The SISCOM methods involve acquiring both ictal and interictal SPECT images of regional cerebral blood flow (rCBF) using a radiolabeled tracer, usually ^{99m}Tc hexamethylpropylene amine oxime or ^{99m}Tc -ethyl cystinate dithylosate (ECD). These functional rCBF maps are then normal-

ized to ensure cerebral pixel intensity to account for differences in total activity and isotope decay, registered using an accurate and robust matching algorithm to account for differences in patient position and slice level and subtracted to produce a functional map of the changes in rCBF during ictus compared with the resting state. This subtraction image is then thresholded to isolate significant blood flow changes and is registered to the patient's MRI image.

One of the major influences on the sensitivity and specificity of the SPECT subtraction image is the accuracy of the icteroheterotaxial SPECT image alignment (7). Poor registration results in subtraction of nonanatomically corresponding voxels. This decreases the sensitivity of the final image by increasing the signal-to-noise ratio and may decrease specificity by producing false-positive activation sites. Brain surface matching techniques (7,8) have traditionally been used to produce subtraction SPECT images (1,2). Surface matching (SM) coregistration consistently matches SPECT images with better than 1 voxel dimension of accuracy (9); however, the literature suggests that even small misalignments may decrease the sensitivity of focal uptake detection (9). Hence, methods that provide more accurate interictal-to-ictal SPECT registration have the potential to further improve the sensitivity and specificity of epileptogenic localization.

The SM algorithm we originally used in SISCOM was developed by Jiang et al. (8) in 1992 and is available as part of the AnalyzeAVW software package (Mayo Foundation, Rochester, MN) (10). This algorithm has been extensively used by many centers and has been demonstrated to be robust and accurate for several different imaging modalities (11–13). Recently, several voxel-based registration algorithms have been proposed for inter- and intramodality image alignment, and these methods have been shown to be even more accurate than SM methods for a variety of applications (14). However, the performance of different algorithms depends greatly on the image modalities used and the registration task to be performed, and few have been compared quantitatively for matching functional rCBF images. In particular, the extensive changes in image contrast that accompany ictal activation could confound voxel-based registration algorithms. Most intramodality voxel-based algorithms depend on a certain consistency of voxel gray

Behavioral Medicine with the Developmentally Disabled J.H. Kedesdy, D.C. Russo, 2013-11-11 Since the late 1960s the behavioral treatment of mentally retarded autistic and other developmentally disabled persons has grown progressively more sophisticated The literature on behavioral treatment has produced effective and clinically significant programs for the reduction of maladaptive behaviors such as tantrums aggression and self injury skills deficits have been remediated through improved programs for language and life skills acquisition and new environments have been opened in the creation of mainstream educational opportunities In spite of these advances it strikes us that this almost exclusive focus on behavior problems and skills remediation has been somewhat myopic and that much of the potential for application of behavioral science to solving problems of the developmentally disabled is as yet untapped In the 1980s an important revolution has taken place the development of the field of behavioral medicine This field in merging disease treatment and management with learning and behavior has already made impressive progress toward a reconceptualization of health care that acknowledges the centrality of behavior in disease expression Although there has as yet been only a preliminary application of this reconceptualization to the field of developmental disabilities we are convinced that further extension has great potential
