

81. THE DIRECT CURRENT CIRCUIT.

A conductor is said to carry a current of 1 ampere if 1 coulomb of electricity passes through a cross-section of it in 1 second. The rate at which the electricity moves was found by Ohm to be proportional to the p.d. and inversely proportional to a quantity which is a property of the dimensions of the wire, its material and its temperature. This property is the resistance R . Ohm's Law is:

$$I = \frac{V}{R} \quad \text{or} \quad \text{AMPERES} = \frac{\text{VOLTS}}{\text{OHMS}}$$

This relationship holds for a part of the circuit or for the entire circuit. In the diagram the current I may be

expressed either as the voltage V read by the voltmeter divided by the resistance R of the resistor or as the electromotive force (emf) E of the battery divided by the total resistance R' of the entire circuit, where R' is the sum of the resistance of the battery (usually relatively small), the ammeter A and the resistor. For a more accurate determination of the effect of the resistance of the voltmeter, its resistance must be considered, but for a high grade instrument it will not be necessary to allow for the parallel connection of the voltmeter and the resistor, since practically all of the current is in the latter.
